The cases of five patients (age range, 13-28 yr) with Bechet's disease, two of which had intestinal ulcers observed by colonfiberscopy, are presented, together with a review of 49 surgically treated cases and 14 cases that occurred with colitis. The symptoms included stomatitis aphthosa, abdominal pain, genital ulceration, uveitis (2 cases), and diarrhea (1 case). In the first patient, a barium enema examination revealed multiple ulcers in the ileocecal region and the ascending, transverse, and sigmoid colon. A repeat barium enema study revealed no ulceration after the administration of a total of 720 mg of paramethasone. Colonofiberoscopy revealed ulceration in the cecum and ileocecal region, and a right hemicolectomy was carried out. Perforated ulcers were found in the ileum and cecum. One year later, another ileal resection was carried out for reperforation of the ileum, and the patient is now doing well. In the second patient, a barium examination revealed ulceration at Bauhin's valve, and colonofiberscopy revealed another ulcer in the terminal ileum. Hemicolectomy, including 50 cm of ileum, was carried out. One year after the operation, recurrent genital ulceration produced a rectovaginal fistula, which necessitated a sigmoidal colostomy. In the third patient, multiple perforations in the cecum and ascending colon, resulting in panperitonitis, were found 4 days after an emergency appendectomy had been performed. Exteriorization, followed 1 yr later by hemicolectomy, was performed, and the patient has been asymptomatic for 7 yr. In the fourth patient, three tumor masses were found in the ileocecal region and ileum. All tumors were covered by omentum. A hemicolectomy was performed, and examination of the resected specimen showed three deep and seven shallow ulcers. The fifth patient underwent resection of the cecum and part of the ileum for sealed perforation of the cecum. The resected specimen showed multiple ulcers with fistulae and many sealed perforations. Microangiograms of the resected specimen of patient 1 revealed that both a penetrated ulcer in the cecum and a partially re-epithelized ulcer in the ileum were avascular, especially at their bases. The authors propose that the impairment of the microcirculation at the site of the vascular network in the submucosal layer might contribute to the development of ulcers.

7612 CONGENITAL CHLORIDE DIARRHOEA WITH FUNCTIONAL ILEUS IN A PREMATURE INFANT. (Eng.) Buts, J. P.; Goenen, M.; Claus, D.; Otte, J. B.; De Meyer, R.; Tremouroux, J. (Cliniques universitaires, St. Joseph, 3020 Herent, Louvain, Belgium). *Helv. Paediatr. Acta* 30(4/5):343-348; 1975.

A case of congenital chloride diarrhea with functional ileus, which was diagnosed in a premature (born at 31 weeks of gestation) male infant of North African parentage on the 5th day of life, is reported. On first physical examination, the patient presented marked abdominal distension with a poor peristalsis. Laboratory results obtained on the 4th and 5th day of life showed very high chloride levels (166 and 199 mEq/l) in the stools, and a diagnosis of congenital chloride diarrhea was made, based on the fact that fecal chloride exceeded the sum of sodium (118 and 141 mEq/l) and potassium (6 and 48 mEq/l) excretion on days 4 and 5, resp. Despite total i.v. feeding (Aminofusin forte, 20 ml/24 hr; Intralipid 20%, 20 ml/24 hr), large amounts of fluids (200 ml/kg/24 hr), and adequate supplies of electrolytes, the stools remained unchanged; severe metabolic acidosis became unresponsive to bicarbonate and tromethamine therapy. On the 6th day, cutaneomucous pallor, dehydration, polyuria (590 ml/24 hr), impaired neurological condition, and respiratory distress suddenly occurred. Thereafter, the patient's condition quickly deteriorated, and he died on the 8th day after birth. Anemia, flaccidity, unresponsiveness, polyuria, and dehydration, which simultaneously occurred on the 6th day of life, were attributed to cerebral hemorrhage. Although this potentially fatal complication is frequent in unaffected preterm infants, it is suggested that the hemoconcentration due to severe osmotic diarrhea and hyperosmolality resulting from bicarbonate therapy, electrolyte infusions, and parenteral feeding might have had a synergic effect on its development.

7613 ZINC DEFICIENCY IN TWO INFANTS DURING TOTAL PARENTERAL ALIMENTATION FOR DIARRHEA. (Eng.) Arakawa, T.; Tamura, T.; Igarashi, Y.; Suzuki, H.; Sandstead, H. H. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Am. J. Clin. Nutr.* 29(2):197-204; 1976.

The occurrence of zinc deficiency in two male infants receiving total parenteral alimentation (TPA) for chronic diarrhea of 3-4-month's duration is reported. The first patient was admitted at 7 months of age, and he received TPA for 10 months, without improvement in the frequency and character of his diarrhea. The other patient was admitted at 3 months of age, and after 6 months of TPA, his diarrhea completely ceased. An acrodermatitis enteropathica-like rash occurred in both infants on the 22nd and 25th day of TPA treatment, resp. The rash consisted of erythema; vesicles; denuded patches; pustules around natural orifices, the genitalia, perineum, fingers, and toes; alopecia; blepharitis; and paronychia. Treatment with zinc sulfate (35 mg/day, p.o.) resulted in the cure of the rash within a few days, as well as in the subsidence of other signs consistent with zinc deficiency (low plasma zinc concentrations and a decline in serum alkaline phosphatase). *Staphylococcus aureus* was cultured from the rash of both infants. A breakdown in repair mechanisms in the skin coupled with an impaired local resistance to *S. aureus* is believed to have caused the rash.

7614 THE ROLE OF ALTERED INTESTINAL PERMEABILITY IN THE PATHOGENESIS OF Salmonella DIARRHEA IN THE RHESUS MONKEY.

(Eng.) Kinsey, M. D.; Dammin, G. J.; Formal, S. B.; Giannella, R. A. (Walter Reed Army Inst. Res., Washington, DC). *Gastroenterology* 71(3):429-434; 1976.

To test the hypothesis that altered intestinal permeability may play a role in *Salmonella* diarrhea, sodium and water transport, erythritol and mannitol clearance into perfused intestinal loops, and changes in transmural electrical potential difference in response to hypertonic intestinal perfusion were studied in male rhesus monkeys infected with *S. typhimurium* (5×10^{10} organisms, p.o.). In the *Salmonella*-infected animals, the morphological changes in the ileum and colon were more striking than those in the jejunum. In the ileum, there was a fulminating, acute, diffuse, inflammatory reaction involving the mucosa and submucosa. In the colon, there was acute diffuse colitis, characterized by inflammatory cell infiltration of the mucosa and submucosa, crypt abscesses, and bacterial invasion of the epithelial cells and lamina propria. In normal controls, water absorption occurred in the jejunum, ileum, and colon, at mean rates of -124.2, -132.9, and -81.1 μl/hr/cm, resp. In the *Salmonella*-infected animals, there was a striking reversal in net water movement in all intestinal sites; water secretion occurred at mean rates of 18.8, 75.5, and 38.9 μl/hr/cm in the jejunum, ileum, and colon, resp. In normal animals, low mean steady state transmural electrical potential differences were obtained in the jejunum and ileum (-1.7 and +1.0 mv, resp.), whereas a high value was found in the colon (-18.0 mv). In the infected animals, the mean potential difference was significantly higher in the ileum and colon (-3.4 and -31.9 mv, resp.). In normal animals administered with hypertonic ^{14}C-erythritol, there was a gradient of diminishing permeability from jejunum, to ileum, to colon, the mean permeability coefficients being 0.193, 0.100, and 0.016 cm^2/hr, resp. When hypertonic ^{3}H-mannitol was injected, the corresponding coefficients were 0.041, 0.026, and 0.025 cm^2/hr. In the *Salmonella*-infected animals, there was no significant increase in permeability over control values in jejunum, ileum, or colon for either erythritol or mannitol; there was significantly diminished erythritol permeability in the jejunum (0.147 cm^2/hr). As a positive control in normal animals, perfusion with 25 mM EDTA increased permeability, resulting in increased plasma-to-lumen isotope flux and no streaming potential in response to hypertonic perfusates. The data show that despite severe alterations in intestinal histology, transmucosal permeability remains unchanged and is not a contributing factor in *Salmonella* diarrhea.

7615 NEONATAL NECROTISING ENTEROCOLITIS.

(Eng.) Davies, M. R. Q. (Red Cross War Memorial Children's Hosp., Cape Town, South Africa). *S. Afr. J. Surg.* 13(2):97-101; 1975.

A review of nine cases of presumed neonatal necrotizing enterocolitis is presented. The patients' ages ranged from 24 hr to 27 days and eight of the neonates weighed less than 2.5 kg on admission. Indications for referral and subsequent surgical intervention were: pneumoperitoneum in six cases, severe localized peritonitis in two cases, and diffuse peritonitis in one case. Abdominal x-ray studies showed ileus in seven cases. Although a pneumoperitoneum was seen in six patients, intestinal pneumatosis was present in only one case. Only three patients survived surgery. In two, early localization of the bowel perforations was present with abscess formation. Simple surgical drainage proved successful in one of these patients, while a surgical drainage procedure was covered by a proximal defunctioning colostomy in the other. Significant ileal gangrene with generalized peritonitis was found in the only other survivor; resection and the construction of a Bishop Koop ileostomy gave satisfactory results. Six patients died of uncontrollable gram negative sepsis. Terminal respiratory failure with an associated consumptive coagulopathy was a common finding. The high mortality rate in this group of patients was attributed to the excessive delay in the diagnosis of the presence of significant intra-abdominal pathology.

7616 BUOYANT DENSITY IN CESIUM CHLORIDE OF THE HUMAN REOVIRUSLIKE AGENT OF INFANTILE GASTROENTERITIS BY ULTRACENTRIFUGATION, ELECTRON MICROSCOPY, AND COMPLEMENT FIXATION.

(Eng.) Kapikian, A. Z.; Kalica, A. R.; Shih, J. W.-K.; Cline, W. L.; Thornhill, T. S.; Wyatt, R. G.; Chanock, R. M.; Kim, H. W.; Gerin, J. L. (Lab. Infectious Disease, Natl. Inst. Allergy Infectious Diseases, Bethesda, MD 20014). *Virology* 70(2): 564-569; 1976.

The buoyant density in cesium chloride of the human reovirus-like (HRVL) agent of infantile gastroenteritis was studied by electron microscopy and complement fixation (CF) to detect the reovirus-like particles in fractions of the density gradient. Virus-positive stool filtrates from three infants, aged 11, 13, and 16 months were studied. Morphologically full reovirus-like particles had a density of 1.35-1.37 g/cm^3, whereas empty particles had a density of 1.29 g/cm^3. Peak CF activity coincided with the peak fraction of both the full and empty reovirus-like particles. CF activity was also associated with the virion and not with a soluble antigen. The density of the human reovirus-like agent in cesium chloride is similar to that observed for the antigenically related Nebraska calf diarrhea virus, the reoviruses, and the bluetongue virus "L" (light) form, which probably represents the mature virion of this orbivirus. In addition, the density of the empty human reovirus-like particles is similar to that reported for the reovirus top component of empty reovirus particles.

GENERAL

Parasitology

7660 Schistosoma mansoni IN BABOONS; III. THE COURSE AND CHARACTERISTICS OF INFECTION, WITH ADDITIONAL OBSERVATIONS ON IMMUNITY. (Eng.) Damian, R. T.; Greene, N. D.; Meyer, K. F.; Cheever, A. W.; Hubbard, W. J.; Hawes, M. E.; Clark, J. D. (Dept. Zoology, Univ. Georgia, Athens, GA 30602). *Am. J. Trop. Med. Hyg.* 25(2):299-306; 1976.

The course and characteristics of *Schistosoma mansoni* infections were studied in 54 baboons. The compatibility of the *S. mansoni-Biomphalaria pfeifferi--Papio cynocephalus* system was evidenced by the infectivity of cercariae to baboons, including a high penetration rate (97.7%) and a high adult worm recovery rate (41.7%). The baboons generally tolerated the infection well, and the worms were long-lived and fertile in these animals. Pathological findings were generally unremarkable except for the observation of a much lower tendency for hepatic granulomas to fibrose, as compared with those in the gut. An acute "toxemic" phase occurred 66 days or less after a large cercarial exposure (1,789-10,000 cercariae) in three baboons. Worm burdens were not significantly reduced during the course of prolonged infections, except in the group of five baboons who were challenged after repeated small exposures ("trickle" infections) over a 3-yr period. An anterior shift in egg deposition sites (from the colon to the small intestine) with longer infection periods was observed in those animals singly infected or repeatedly exposed to *S. mansoni*. Prolonged infection also resulted in decreased oviposition by worms. Decreased oviposition and the anterior shift may be the result of a second phase of immunity distinct from the concomitant immunity also observed in the baboon infections. As is true of man, the baboon and grivet monkey are slow to develop immunity. Thus baboons and grivet monkeys may be successfully employed as experimental models for human schistosomiasis, particularly in the study of its immunological aspects. The delayed immunity may allow one to dissociate the effects of fairly chronic infections from those of protective immunity.

GENERAL

Regional Enteritis

7670 SEASONAL VARIATIONS IN THE CLINICAL PRESENTATION OF CROHN'S DISEASE AND ULCERATIVE COLITIS. (Eng.) Cave, D. R.; Freedman, L. S. (St. George's Hosp. Medical Sch., Hyde Park Corner, London, S.W.1, England). *Int. J. Epidemiol.* 4(4):317-320; 1975.

The cases of 211 patients with Crohn's disease and 201 patients with ulcerative colitis were studied to determine if there is a seasonal variation in the onset of the disease. It was demonstrated that Crohn's disease has a peak onset in January and July, whereas ulcerative colitis has a possible peak of onset in December. These findings suggest that there are environmental factors, perhaps an infective agent, involved in the etiology of Crohn's disease and that these may be different from the factors involved with ulcerative colitis.

7671 ANGIOGRAPHIC SPECTRUM IN CROHN'S DISEASE OF THE SMALL INTESTINE AND COLON. (Eng.) Miller, M. H.; Lunderquist, A.; Tylen, Y. (Dept. Diagnostic Radiology, Univ. Hosp., Lund, Sweden). *Surg. Gynecol. Obstet.* 141(6):907-914; 1975.

Barium and angiographic examinations of the small intestine and colon were performed (within 1 month of each other) in 34 patients with histopathologically verified Crohn's disease. Patients were examined before (23) or after (11) resection of the intestine. Barium examination of the small intestine was abnormal in 18 preoperative patients. Two patients in the nonstenotic stage demonstrated mucosal edema but no destructive changes of the vasa. The 16 patients in the stenotic stage had a definite narrowing of the intestine and morphologic changes of the vasa, ranging from irregularity to complete occlusion of the stem. A distinctive angiographic pattern was present in the distal small intestine of patients with advanced narrowing. Barium and angiographic examination of the colon demonstrated no significant narrowing in five nonstenotic patients. All patient demonstrated a hypervascular blood supply to the colon, and in contrast to the small intestine, lumen irregularities of the vasa were limited mainly to the distal portion of the mural vasa, rather than the entire length. Four stenotic patients demonstrated advanced narrowing of the colon, but the vas crossing the colon were narrow, indicating the absence of hypervascularity. In the 11 postresection patients, the barium examination was positive for recurrent disease in all patients, but the angiogram d umented extension of disease in three patients in areas appearing normal at barium examination. At angiography, the colon was hypervascular distal to the anastomosis as a skip lesion in two patients in whom the barium enema was normal.

7672 COLLAGEN PEPTIDASE IN CROHN'S DISEASE. (Ger.) Shalev, E.; Stojan, B.; Fahrlander, H. (Departement Innere Medizin der Universitat, Kantonsspital, CH-4004 Basel, Spitalstr. 21, Switzerlan *Dtsch. Med. Wochenschr.* 101(18):685-687; 1976.

Based on the histological similarity of Crohn's disease (CD) and sarcoidosis and the role of collagen peptidase (CP) in sarcoidosis diagnosis, the role of CP in CD has been studied. The clinical sample included 71 CD patients, 40 of whom had received surgery, and 21 were under immunosuppressive management. CP was elevated in 54 patients, normal in 13, and decreased in 4 CD patients. The mean value was 36.7 clinical U/ml serum for CD patients and 24.4 clinical U/ml for the control group (24 subjects), a significant difference of $p<0.001$. The average CP level in the surgically and nonsurgically treated CD groups was 39.3 and 33.5 clinical U/ml, resp., both of which are significantly higher than control values ($p<0.001$). The average serum CP levels and their significance in the subgroups receiving immunosuppressive and not receiving immunosuppressive therapy was 29.5 clinical U/ml ($p<0.025$) and 39.7 clinical U/ml ($p<0.001$), resp. The CP level in the group not treated by immunosuppressives was very significantly ($p<0.001$) increased over the treated group and the CP level in the surgical group was also significantly ($p<0.05$) increased over the nonsurgical group. As in sarcoidosis, elevated CP is an expression of increased collagen turnover, compatible with the histological picture of increased collagenous stroma in the intestinal wall.

7673 RARE FISTULA FORMATION IN CROHN'S ENTEROCOLITIS REGIONALIS. (Ger.) Morl, M.; Fuchs, H.; Riemann, J. (Stoffwechselklinik der LVA Wurttemberg, D-6990 Bad Mergentheim, W. Germany). *Med. Klin.* 71(19):814-819; 1976.

Five case histories are reviewed to illustrate the complicating effect of abscess and fistula formation on the diagnosis of Crohn's disease (CD). A 25-yr-old woman with a 12-yr history of gastrointestinal problems uncorrected by terminal ileum resection and ileotransverscolostomy without colonic resection presented with a rectovaginal fistula, mucosal ulceration, and submucosal fibrosis typical of CD. Colonoscopy revealed sigmoid stenosis, rectosigmoid pseudopolyps, and CD recurrence 70 cm rostral to the anastomosis in the terminal ileum. Some fistula regression followed long-term corticosteroid therapy. Subtotal colectomy with partial ileal resection and ileorectostomy were performed after discovery of periproctitic fistulas and a fistula system between the greater curvature of the stomach and abscess cavities in the spleen bed. A 33-yr-old woman with a similar history of CD presented with a 10-cm long fistula between the terminal ileum and right third of the transverse colon. Progressive formation of small bowel inflammatory tumor conglomerates was associated with a right hydronephrosis. The tumor tissue and fistula system were removed and an ileotransversostomy was performed. A 31-yr-old woman with a recent history of CD was found to have several fistulas from the rectosigmoid transition to the terminal ileum, without stenosis or abscess. Surgery was not indicated. The fourth patient, a 25-yr-old woman with suspected CD developed intractable pain radiating from the lumbar region through the right limb. An abscess over the right gluteus maximus was found to empty into the rectum via a foxhole fistula system. Prognosis after ileohemicolectomy is doubtful. The final case concerns a 48-yr-old woman with a history of periproctitic fistulas presenting with CD and a large rectovaginal fistula. Conservative management with salazosulfapyridine and corticosteroids led to general improvement and some fistula regression. Exact radiological and endoscopic articulation of fistula systems is required before surgical intervention.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tra Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The numbe and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-31
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International · Standard ISO833, 1974,* are used. The two-letter state abbreviations are based on the United States Postal Service Code.

ml, μl	milli-, microliter(s)		

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

7680 FURTHER HISTOPHYSIOLOGICAL OBSERVATIONS ON THE LOWER ESOPHAGUS OF THE RABBIT. (Eng.)

Cecio, A.; Califano, G.; Lobello, R. (Istituto Anatomico, Via Veterinaria 1, 80137, Naples, Italy). *Cell Tiss. Res.* 168(4):475-488; 1976.

Previous neurohistological studies were extended to include the structures contained solely or mainly within the junctional esophageal segment that may play an important role in the sphincter mechanism. Cross sections from the cervical, thoracic, and abdominal segments of the esophagus of 18 rabbits were examined. There was a progressive thickening of the muscularis mucosae from the cervical to the caudal end of the esophagus. The circular muscle layer showed a progressive thickening from the cervical to the abdominal segment. There were abundant and close interconnections between the esophageal striated fibers and gastric smooth muscle cells. Helico-spiral thin elastic fibers were found within the esophageal wall, and the number of these fibers was greatly increased at the gastroesophageal junction. In this area, they occurred mostly within the middle muscle layer. These fibers were wrapped around bundles of musculature describing coils of variable diameters. From the cervical to the abdominal esophagus, there was an increase in the intramural nerve component, particularly Auerbach's plexus; the Auerbach's plexus consisted of a continuous nervous layer containing twice as many neurocytes as the upper esophageal segments. The motor endplates were abundant in the esophagus, particularly within the circular muscle layer of the junctional segment. These endplates often possessed ultra-expansional fibers and secondary endplates. The authors conclude that the neurohormonal factors and their related structures are the most important entities in understanding the sphincterial mechanism of the esophagogastric junction.

7681 THE DISTRIBUTION OF ARGYROPHILE AND ARGENTAFFIN CELLS IN THE SMALL INTESTINE OF RABBITS. (Eng.)

Dhall, U. (Dept. Anatomy, Medical Coll., Rohtak, India). *Anat. Anz.* 138(5):385-391; 1975.

The distribution of enterochromaffin cells was studied in the small intestine of six rabbits, and this pattern was compared with that reported in other species. The patterns of distribution of the argyrophile and the argentaffin cells in each rabbit are illustrated. The highest density of both argyrophile and argentaffin cells occurred in the proximal small intestine. Proceeding caudally from the duodenum, the density of the argyrophile cells decreased sharply over the proximal one third. Thereafter, in the distal two-thirds of the small intestine, the curve of distribution leveled off in one animal and showed a very gradual fall in the other five. The density of the argentaffin cells also decreased in the proximal third of the intestine, although this drop was not as marked as that of the argyrophile cells. In most of the animals, the curves of distribution of both argyrophile and of argentaffin cells showed several waves of rising and falling. A review of the literature reveals that there are con derable species variations in the distribution of argyrophile and argentaffin cells.

7682 DEVELOPMENT OF THE SMALL INTESTINE IN T HYPOPHYSECTOMIZED RAT. II. INFLUENCE CORTISONE, THYROXINE, GROWTH HORMONE, AND PROLACT (Eng.)

Yeh, K.; Moog, F. (Dept. Biology, Washington Univ., St. Louis, MO 63130). *Dev. Biol.* 47(1 173-174; 1975.

The influence of daily doses of cortisone 50 μg/g body weight, thyroxine 1 μg/g body weight, or gro hormone (or prolactin) 20 or 500 μg on the develo ment of the small intestine in the hypophysectomi rat was investigated. The intestinal deficiencie caused by hypophysectomy of NLR rats at 6 days of were repaired to varying degrees by thyroxine or tisone but not by growth hormone or prolactin. A istration of thyroxine alone from 19-22 days rais duodenal alkaline phosphatase activity to normal levels at 24 days. It had a strong effect on jejunal sucrase and maltase, although these activit remained below those of controls. Thyroxine increased the rough endoplasmic reticulum markedly restored the Golgi complexes to their normal conf uration. It intensified the periodic acid-Schiff (PAS) stainability of the brush border. Cortison given from 19-22 days, elevated sucrase and malta activities to normal levels but did not fully restore phosphatase activity. It intensified stai of the brush border and increased the rough endoplasmic reticulum. It seemed to stimulate Golgi activity, but a variety of abnormal forms were p duced. Neither growth hormone nor prolactin for 23 days had any effect on growth. The defects i Golgi configuration, brush border carbohydrate c tent, and activity of the glycoprotein enzymes b to the brush border may all reflect impaired gly sylation in the hypophysioprivic state. The res of thyroxine or cortisone administration suggest that both may affect glycosylation but in differe ways.

7683 THE EFFECT OF S-2-(3-AMINOPROPYLAMINO) PHOSPHOROTHIOIC ACID (WR-2721) ON INTE NAL CRYPT SURVIVAL. II. FISSION NEUTRONS. (En

Sigdestad, C. P.; Connor, A. M.; Scott, R. M. (U Louisville Sch. Medicine, 500 South Floyd St., L ville, KY 40201). *Radiat. Res.* 65(3):430-439; 1

The ability of S-2-(3-aminopropylamino)ethylphos rothioic acid (WR-2721) to protect against fissi neutron irradiation was tested in the intestinal crypts of male C57/Bl 6-J mice. The mice were i jected i.p. with WR-2721 (500 mg/kg) at 0.25, 0. 1, 2, 4, 12, and 24 hr prior to neutron irradiat (300 rads). The mice were sacrificed 3 days lat Unirradiated mice had a mean level of 940 crypts while unprotected irradiated mice had 376 crypts WR-2721 pretreatment protected against the decre in crypts, and the protective efficacy peaked at about 1 hr after the injection; there was a rapid fall in this protective effect when WR-2721 was injected 12 hr prior to irradiation. Unprotected mice had a LD$_{50}$ of 253 rads, while mice pretreated with WR-2721 had a LD$_{50}$ of 392 rads. The dose modification factor (DMF), calculated as a ratio of protected to unprotected LD$_{50}$ values, was 1.6. The intestinal crypt survival curve in unprotected mice had a D$_0$ of 95 rads, with a shoulder of 156 rads. In the curve of pretreated mice, the D$_0$ was 154 rads, which was significantly different from the control curve. The DMF, calculated as a ratio of equally effective doses to reduce crypt survival to 50% of control level, was 1.3. Studies of the effect of WR-2721 on cellularity revealed that the mean unirradiated control values of disintigrations per min (dpm) per crypt and per milligram of intestine were 13.2 and 12,496 dpm, resp.; WR-2721 protected the intestine from about 120-140 rads of fission neutrons, resulting in a DMF between 1.4 and 1.5. The results demonstrate the ability of WR-2721 to protect the intestinal mucosa against fission neutron irradiation.

7684 SCANNING ELECTRON MICROSCOPY OF MOUSE INTESTINAL MUCOSA AFTER COBALT 60 AND D-T NEUTRON IRRADIATION. (Eng.) Hamlet, R.; Carr, K. E.; Toner, P. G.; Nias, A. H. W. (Glasgow Inst. Radiotherapeutics and Oncology, Belvidere Hosp., Glasgow G31 4PG, Scotland). *Br. J. Radiol.* 49(583): 624-629; 1976.

The small intestinal epithelium of adult C3H mice was studied by scanning electron microscopy (SEM) 3.5 days after exposure to single doses of D-T neutrons (0-1,000 rads) or ^{60}Co gamma irradiation (0-2,000 rads). Dose response curves of crypts per circumference for both sources of irradiation had similar slopes (D$_0$=180 for gamma irradiation and 150 for neutrons), and both curves showed large shoulders. The first significant deviation from the shoulder occurred at approximately 1,000 rads for ^{60}Co irradiation and at about 500 rads for D-T neutrons. With gamma irradiation, the first changes seen with SEM occurred after doses of 300 rads and consisted of minor distortion at the tips of some villi. Early changes were observed after 170 rads of neutrons had been given and consisted of slight swelling and broadening of the villi and a distinct irregularity of surface creases. At shoulder doses, gamma irradiation produced inconsistent orientation of the villi and clumping of groups of villi. Individual villi were more often bent or twisted than in control samples, and the villi tips were often misshapen to a greater degree than their proximal portions. Shoulder doses of D-T neutrons produced irregularity in the disposition of the surface markings and a more conical villus profile than in controls or gamma-irradiated villi. With both types of irradiation, the morphological changes intensified with increasing doses. It is concluded that SEM provides a more sensitive indicator of mucosal irradiation damage at low dose levels than conventional quantitative techniques. It is also suggested that mucosal morphology may provide a means of discriminating between the effects of different types of radiation at dose levels which are radiobiologically equivalent on certain quantitative scales.

7685 KINETICS AND POSSIBLE REGULATION OF CRYPT CELL POPULATIONS UNDER NORMAL AND STRESS CONDITIONS. (Eng.) Potten, C. S. (Christie Hosp. and Holt Radium Inst., Manchester M20 9BX, England). *Bull. Cancer (Paris)* 62(4):419-430; 1975.

Studies of the proliferative organization of mouse intestinal epithelial crypts are reviewed. About half of the 250-260 crypt cells are proliferative cells. The lower portion of the crypt contains about 40-50 relatively dormant cells and 10-15 functional Paneth cells. Several studies have suggested that the lower portion of the crypt contains a minority population of cells that are true stem cells, i.e., they provide an input of cells for the larger proliferative compartment higher up the crypt. The presumptive stem cells may be pluripotent and produce Paneth, goblet, and columnar cells. They are probably also the cells that are capable of regenerating the crypt after x-ray depopulation. Radiobiological experiments indicate that the number of cryptogenic cells is less than 80, while the results of several kinetic experiments indicate that the number of stem cells is about 20. The stem cells are located in the Paneth cell zone of the crypt, and are apparently passing through the cell cycle at about half the speed of the proliferative cells. It is these vital stem cells that will determine the response of the mucosa to therapeutic agents, probably play a role in carcinogenesis, and play a dominant role in mechanisms controlling cell proliferation.

7686 THE TIME-COURSE OF CHANGES IN MUCOSAL ARCHITECTURE AND EPITHELIAL CELL PRODUCTION AND CELL SHEDDING IN THE SMALL INTESTINE OF THE RAT FED AFTER FASTING. (Eng.) Clarke, R. M. (Dept. Human Morphology, Univ. Park, Nottingham NG7 2RD, England). *J. Anat.* 120(2):321-327; 1975.

The time course of changes in mucosal architecture and epithelial cell production and cell shedding in the small intestine of rats fed after fasting was investigated. Male albino Wistar rats were starved for 3 days and then allowed access to low-residue food. Controls continued to fast. Villus height, crypt depth, crypt/villus ratio, rate of cell production per crypt, and number of epithelial cells shed per villus in 5 min were measured in both groups 0.5, 1, 2, 4, 6, 9, 12, 16, and 24 hr after refeeding. Villus height increased 2 hr after refeeding and was significantly greater than starved controls (400 and 350 μm, resp., $p<0.05$). Crypt depth changed less dramatically, and the crypt/villus ratio was unchanged. The number of shed cells per villus was reduced within 0.5 hr of refeeding ($p<0.05$ for 0.5- and 1-hr values), and remained at a low level until 3 hr. At 9 hr, this number was significantly increased (i.e., 65 cells versus 32 in control $p<0.01$). The cell production rate in refed rats was not increased until 12 hr, when it rose to 23.3 cells/crypt/hr, significantly greater than controls

(11.3, p=0.02). No evidence for a reserve of cells in G_2 was found, and the 3-hr lag between the increases in cell shedding and cell production would probably not give enough time for cells in G_1 to pass through S and G_2. In conclusion, these observations do not support the hypothesis that increased cell shedding from the top of the villus stimulates increased cell production in the crypts of Lieberkuhn.

7687 ORGANIZATION OF AN ACTIN FILAMENT-MEMBRANE COMPLEX: FILAMENT-POLARITY AND MEMBRANE ATTACHMENT IN THE MICROVILLI OF INTESTINAL EPITHELIAL CELLS. (Eng.) Mooseker, M. S.; Tilney, L. G. (Dept. Biology, Univ. Pennsylvania, Philadelphia, PA 19174). *J. Cell. Biol.* 67(3):725-743; 1975.

The brush border of chicken intestinal epithelial cells was investigated to gain further information about the interaction of actin filaments with membranes. Through the analysis of isolated, demembranated brush borders decorated with the myosin subfragment, S_1, all the microvillar actin filaments were found to have the same polarity. The S_1 arrowhead complexes pointed away from the site of attachment of actin filaments at the apical tip of the microvillus membrane. In addition to the end-on attachment of actin filaments at the tip of the microvillus, these filaments were also connected to the plasma membrane all along their lengths by periodic (33 nm) cross bridges. These bridges were best observed in isolated brush borders incubated in high concentrations of Mg^{++} (10-40 nM). Their visibility was attributed to the induction of actin paracrystals in the filament bundles of the microvilli. Evidence for the presence of myosin-like filaments in the terminal web region of the brush border was obtained.

7688 ELECTRON MICROSCOPY OF KUPFFER CELLS IN THE ORTHOTOPIC PORCINE LIVER HOMOGRAFT DURING THE LATE STAGE AFTER TRANSPLANTATION (PHAGOCYTOSIS OF HOST CELLS BY KUPFFER CELLS). (Eng.) Cossel, L. (Pathologisches Institut der Karl-Marx Universitat, Liebigstrasse 26, 701 Leipzig, E. Germany). *Exp. Pathol. (Jena)* 11(3/4):168-181; 1975.

Electron microscopical observations of macrophages (Kupffer cells) in an orthotopic porcine liver homograft in the late stages after transplantation are described. The tissue was removed by exploratory excision made during laparotomy 138 days after transplantation. Numerous macrophages were found on the surface of, or within the endothelial sinusoid lining. Their preferential position was in the periphery of the lobe. The macrophages had a variable number of microvilli- or pseudopodia-like processes. They contained roundish or elongated nuclei with relatively deep indentations, focally dilated perinuclear spaces, a well-developed endoplasmic reticulum with focally enlarged cisterns, numerous ribosomes, large Golgi complexes, numerous vesicles, vacuoles, polymorphous cytosomes, and elongated mitochondria. Close topographical relations of the macrophages to hepatocyte debris, RBC, thrombocytes, granulocytes and lymphocytes, with contact of their cell membranes, were found. Light and electron microscopy demonstrated features of a late rejection, i.e., chronic aggressive hepatitis with transition to cirrhosis. The results showed that in late stages after liver transplantation, at the time of compensated function during late rejection, both phagocytosis and a degradation of erythrocytes, thrombocytes, and probably, also lymphocytes by the macrophages occur.

7689 MORPHOMETRIC STUDIES ON THE RAT LIVER IN BILIARY OBSTRUCTION. (Eng.) Yamauchi, H.; Koyama, K.; Otowa, T.; Ouchi, K.; Anezaki, T.; Sato, T. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 119(1):9-25; 1976.

Morphometric studies were carried out in the livers of Wistar rats with biliary obstruction. The common bile ducts were ligated and severed, and liver biopsies were done weekly for 7 postoperative weeks. With persistent biliary obstruction, the tissue constituents of biliary ducts proliferated markedly, and the volume ratio of the hepatic parenchyma showed a drastic decrease with time. The elevated mean sectional area of the nucleus, the increased mitotic index, and the unchanged estimated weight of the hepatic parenchyma after biliary obstruction suggested that lost hepatocytes were compensated for by regeneration. In the livers with biliary obstruction, the mitochondria were swollen and increased in number. In addition, the cristae were irregularly oriented and tortuous. Dilatation of the rough and smooth endoplasmic reticulum, dilation of the bile canaliculi, and increased numbers of lysosomes were also found. In controls, mitochondrial counts were 50-60%, and the volume index was 18.0%; in the livers with biliary obstruction, these levels were increased to 70-80% and 25.0%, resp. These increases corresponded to the duration of biliary obstruction. The results suggest that there is mitochondrial hypofunction in the hepatocytes of cholestatic livers.

7690 MORPHOMETRIC ANALYSIS OF PANCREATIC ACINAR CELLS FROM ORALLY FED AND INTRAVENOUSLY FED RATS. (Eng.) Pavlat, W. A.; Rogers, W.; Cameron, I. L. (Dept. Anatomy, Univ. Texas Health Science Center at San Antonio, San Antonio, TX 78284). *J. Surg. Res.* 19(4):267-276; 1975.

The effects of 1 week of total parenteral (i.v.) nutrition on the pancreatic acinar cells of four male Buffalo rats were investigated. Four other rats were fed p.o. (controls). Stereological morphometric analysis of the cells showed that the relative nuclear volume of both groups of rats was not significantly different. The ergastoplasmic region of the i.v. fed rats occupied a significantly ($p<0.05$) smaller amount of the total acinar cell volume than the controls. Conversely, the zymogenic region of the i.v. group was significantly ($p<0.05$) increased. The average volumes (in μm^3) of the cellular components for controls and i.v. fed rats were: cell volume, 22.230, 10,295; mean nuclear volume, 941, 475; cytoplasmic volume, 21,289, 10,450; zymogenic region (electron microscopy level), 5.269, 3.418;

ergastoplasmic region, 16,020, 7,032; zymogenic region (1-μm thick sections), 6,502, 4,450; and ergastoplasmic region, 14,836, 6000; resp. Apparently, the cells of i.v. fed rats maintain an adequate store of zymogen and simultaneously show morphological evidences of lower synthetic activity. Total i.v. feeding may be of use in treating pancreatic disease by relieving the acinar cells of their normal function, allowing healing to occur.

7691 ELECTRON MICROSCOPIC STUDY OF ACINAR CELLS OF THE SUBMAXILLARY SALIVARY GLANDS OF ALBINO RATS. (Rus.) Kalinin, V. I.; Nevorotin, A. I. (Dept. Therapeutic Stomatology, Central Res. Lab., Pavlov First Medical Inst., Leningrad, USSR). *Arkh. Anat. Gistol. Embril.* 68(7):63-67; 1975.

7692 HISTOCHEMICAL AND ULTRASTRUCTURAL ALTERATIONS OF THE DUODENUM IN ACUTE HYPOXIA. (Eng.) Jozsa, L.; Szekely, O.; Reffy, A. (National Inst. Traumatology, H 1430 Budapest, P.O. Box 21, Hungary). *Z. Exp. Chir.* 9(3):168-179; 1976.

7693 MORPHOLOGICAL ANALYSIS OF THE PHENOMENON OF DENUDING OF THE VILLI IN ENTERIC FORM OF ACUTE RADIATION SICKNESS. (Rus.) Parshkov, E. M.; Brodsky, R. A. (Res. Inst. Radiology, USSR Acad. Medical Sciences, Obninsk, USSR). *Biull. Eksp. Biol. Med.* (11):113-116; 1975.

ABSORPTION - EXCRETION - TRANSPORT

7698 EFFECT OF ACUTE INTESTINAL OBSTRUCTION ON THE LEAKAGE OF ALBUMIN FROM BLOOD INTO THE SMALL INTESTINE. (Eng.) Herczeg, B. (First Dept. Surgery, Semmelweis Univ. Medical Sch., Budapest, Hungary). *Acta Chir. Acad. Sci. Hung.* 16(1):27-37; 1975.

The effect of a simple, low intestinal obstruction on the leakage of ^{131}I-serum albumin from the circulation into the intestine was investigated in dogs. A median laparotomy was performed 24 hr after administration of 100 μCi human ^{131}I-albumin. Portions of the duodenum, jejunum, and ileum were separated, clamped, and catheterized. The intestine was filled with a 5-mg/ml labeled albumin solution and, after 2 hr, the clamps and catheter were removed and the intestine was ligated at the terminal ileum to obstruct the intestinal canal. The experiment was repeated 5 days later. Perfusate samples were precipitated with equal volumes of 20% trichloroacetic acid (TCA), 5% phosphotungstic acid (PWA), and 10% $AgNO_3$. The presence of albumin was demonstrated in every segment examined on the basis of solubility of the TCA precipitate in 95% ethanol and by paper electrophoresis. In the distended segment of the intestine above the ligation, a threefold increase in protein-bound radioactivity, from a normal value of 0.082 to 0.267 ml/10 cm intestine/hr, was observed. Albumin leakage values did not change in the duodenum and jejunum, which were not as involved in the distension, and in the ileal segment below the ligation. The increased albumin leakage observed during intestinal obstruction resulted in a 33% increase in total catabolism.

7699 ABSORPTION FROM A MIXTURE OF SEVENTEEN FREE AMINO ACIDS BY THE ISOLATED SMALL INTESTINE OF THE RAT. (Eng.) Gardner, M. L. G.

)ept. Biochemistry, Univ. Edinburgh Medical Sch., eviot Place, Edinburgh EH8 9AG, Scotland). *J. Phyiol. (Lond.)* 255(2):563-574; 1976.

he absorption and secretion from a mixture of 17 ree amino acids at low concentration (1.6 mM total) ere measured in isolated perfused rat small intesine to determine the absorption mechanism. The cid mixture, which approximated the free amino acid raction of casein hydrolysate, included: aspartic cid, threonine, serine, glutamic acid, proline, lycine, alanine, valine, methionine, isoleucine, eucine, tyrosine, phenylalanine, histidine, lysine, rginine, and tryptophan. The absorption rate of n amino acid was found to be proportional to its oncentration in the perfusate and independent of its hemical constitution. Individual ratios were not ignificantly different (p>0.02) than those observed reviously, when the perfusate contained peptides s well as amino acids. Amino acids were concenrated an average of six times during passage across he mucosa, and the free amino acid composition of he secretion into the tissue fluid was very similar o that of the luminal perfusate. Peptides do not ppear to be added to the tissue fluid during absorpion of free amino acids. It is concluded that the echanisms for free amino acid absorption are indeendent of those for peptide absorption.

700 THE POTENTIAL ROLE OF PROTEIN IN THE ABSORPTION OF FAT. (Eng.) Meyer, J. H.; Stevenon, E. A.; Watts, H. D. (Veterans Admin. Hosp., 16111 lummer St., Sepulveda, CA 91343). *Gastroenterology* 0(2):232-239; 1976.

tudies were carried out to test the ability of proeins and various protein digests to stabilize emulions of triglyceride, the susceptibility of such rotein-stabilized emulsions to lipolysis, and the apability of rats lacking luminal bile salts to bsorb fat from perfused emulsions of triglyceride tabilized with protein. When triglyceride emulsions ere allowed to stand at 68 F with various proteins, rotein digests, or taurocholate, considerably more at remained dispersed over a 2 min-2 hr period than hen the triglycerides were emulsified in saline or mino acid solutions. Sodium taurocholate (10 mM) tabilized corn oil emulsions considerably better than did protein or protein digests, and significantly more fat remained dispersed after 2 hr (27%). Corn oil (5.0 ml) was emulsified in 25 ml of 0.15 M NaCl, 25 ml of exogenous protein [bovine serum albumin (0-15.4 mg/ml) or a 1:1 mixture of bovine hemoglobin with ovalbumin (0-18.2 mg/ml)], or 25 ml of pancreatic or Heidenhain pouch juice diluted in various volumes of 0.15 M NaCl (endogenous protein). Proteins from both exogenous and endogenous sources effectively stabilized the triglycerides, and with all proteins, there was a significant correlation between the percentage of corn oil emulsified and the protein concentration in the aqueous (bulk) phase. This phenomenon of emulsion stabilization by protein was not confined to triglycerides high in unsaturated fatty acid content, as the bovine hemoglobin/ovalbumin mixture (HB-OV) also stabilized emulsions made from triglycerides high in saturated fatty acids (2:1 lard-corn oil mixture). Peptic digestion of the HB-OV did not alter the ability of the protein to stabilize corn oil emulsions. Further digestion with pancreatin resulted in a loss of the emulsifying power of HB-OV; however, the optical densities at 650 nm of the digest-stabilized emulsions were significantly greater ($p < 0.001$) than those of corn oil emulsified in saline. Emulsion stabilization by peptic digests of protein still persisted, despite alterations in pH from 1-7. Such emulsions were capable of being hydrolyzed by pancreatic lipase, and could be absorbed from the gut of bile-deficient rats. These emulsions also increased the initial rates of fat absorption from animals with an intact bile supply. It is concluded that the stabilization of luminal emulsions by dietary or endogenous protein may facilitate fat absorption similar to the manner in which detergent-stabilized emulsions have been previously shown to facilitate fat absorption.

7701 ROLE OF MEMBRANE COMPONENTS, GLYCOCALYX AND LIPID IN ABSORPTION OF WATER-SOLUBLE DYES FROM THE RAT SMALL INTESTINE. (Eng.) Nakamura, J.; Yoshizaki, Y.; Yasuhara, M.; Kimura, T.; Muranishi, S.; Sezaki, H. (Faculty Pharmaceutical Sciences, Kyoto Univ., Yoshida Shimoadachi-cho, Sakyoku, Kyoto, Japan). *Chem. Pharm. Bull. (Tokyo)* 24(4):691-697; 1976.

Investigations were made of the role of membrane components in the absorption of four water-soluble dyes, methylene blue (MB), bromthymol blue (BTB), bromphenol blue (BPB), and phenol red (PR), from the rat small intestine. Isolated small intestine from male Wistar albino rats was incubated for 30 min in 1 mg/ml papain and then for 5 min with 0.1 mM dye solution. Control tissues were not subjected to papain digestion. Uptake of MB, BTB, and BPB by the everted sac was reduced 14.0%, 21.3%, and 26.5%, resp., by digestion with papain. No effect was found with PR. In studies of the binding to the brush borders, papain reduced the binding of BPB and BTB significantly, but not MB and PR. Papain had similar effect on the uptake by isolated epithelial cells. When the binding to released components was examined, more MB and BTB were bound than BPB and PR, poorly absorbable dyes. The results suggest that the membrane component contributing to the dye binding to the brush borders is the glycocalyx (surface coat). Lipids, other major membrane components, were extracted from rat intestinal mucosa and separated into neutral lipid (NL), glycolipid (GL), phosphatidylcholine, and phosphatidylethanolamine fractions. Each fraction was dissolved in chloroform, and the partitioning behavior of the dyes was examined using a nonemulsifying system. The extent of dye transfer from the aqueous phase into the lipid fractions containing GL and total lipid (TL) was correlated to the extent of net absorption and tissue accumulation, resp. It is concluded that both lipid and glycoprotein contributed to the accumulation of dyes in the intestinal mucosa.

7702 EFFECT OF CALCIUM ON MAGNESIUM ABSORPTION.

(Eng.) Behar, J. (Dept. Medicine, Veterans Hosp., West Haven, CT 06516). *Am. J. Physiol.* 229(6):1590-1595; 1975.

The effect of Ca on Mg absorption in relation to changes in Na and water absorption was investigated in the rat ileum *in vivo.* Solutions of 150 mM NaCl, 5 mM KCl, 0.5-32 mM MgCl$_2$, and 0-4 mM CaCl$_2$ were perfused into the terminal ileum of male albino Charles River rats. An increase in Ca concentration from 2 to 4 mM led to a progressive decrease in the lumen-to-plasma transport of Mg at 0.5-0.32 mM Mg. The association of Mg transport and Mg concentration (0.5-0.16 mM) was linear for 2 mM Ca ($p<0.001$) and 4 mM Ca ($p<0.001$) and remained so up to 32 mM Mg and 4 mM Ca ($p<0.001$). Net Na and water absorption also decreased with increasing concentration of Ca. This effect of Ca was also observed when NaCl was replaced by urea. However, a consistent correlation was observed between the magnitude of net Mg absorption and the rates of net water absorption at all Ca concentrations. Ca probably decreases Mg absorption by reducing the membrane permeability to solutes that induce net water flow nonspecifically, regardless of type of transport. These findings are consistent with the concept that Mg is transported by solvent "drag." An increase of Ca in the lumen increased the tissue accumulation of Mg, which was associated with a decrease in net Na absorption and in the negativity of the transmural potential difference. An additional mechanism of Mg transport that operates independently of net water flow is suggested.

7703 ANALYSIS OF THE ROLE OF ENDOGENOUS PROLACTIN ON FLUID AND SODIUM CHLORIDE ABSORPTION BY THE RAT JEJUNUM.

(Eng.) Mainoya, J. R. (Dept. Zoology, Univ. Dar-es-Salaam, Dar-es-Salaam, Tanzania). *J. Endocrinol.* 67(3):343-349; 1975.

The influence of endogenous prolactin on intestinal absorption of fluid and NaCl was investigated in everted jejunal sacs of male Sparague-Dawley rats. Hypophysectomy in nine rats significantly decreased the mean levels of intestinal fluid absorption (0.57 ml/g wet weight/hr in jejunal segment III) and sodium transfer (54.8 μEq/g/hr) from those in controls (1.15 ml/g/hr and 137.5 μEq/g/hr, resp.). The chloride level was unchanged. Pituitary implantation in both normal and hypophysectomized rats increased fluid, sodium, and chloride absorption (1.88 ml/g/hr, 216.3 μEq/g/hr, and 103.3 μEq/g/hr, resp., in the normal animals with implant; 1.46 ml/g/hr, 173.8 μEq/g/hr, and 103.2 μEq/g/hr, resp., in hypophysectomized animals with implant). Treatment with s.c. estradiol benzoate (5.0 μg), reserpine (25.0 μg), or ergocryptine (60.0 μg) daily for 6 days resulted in increased fluid and sodium absorption. Chloride absorption was also significantly increased by these treatments. In hypophysectomized rats, the estrogen treatment had no effect on intestinal fluid or NaCl absorption. Although adrenalectomy produced no significant changes in absorption, treatment of adrenalectomized rats with prolactin (1.0 mg, 48 and 24 hr before sacrifice), estrogen, or reserpine enchanced fluid, sodium, and chloride transport. The mucosal fluid transfer was 0.90, 1.28, 1.26, and 1.42 ml/g/hr in controls and in adrenalectomized rats treated with prolactin, estrogen, and reserpine, resp.; the mucosal sodium transfer was 119.0, 174.6, 168.0, and 172.7 μEq/g/hr, resp.; and the mucosal chloride transfer was 42.4, 62.4, 70.8, and 65.0 μEq/g/hr, resp. It appears that the effects of ergocryptine in intact rats might be mediated via the pituitary-adrenocortical system, since it stimulated intestinal absorption in intact animals but had no effect on that in adrenalectomized rats. Corticosterone treatment (1.0 mg, s.c., 48 and 24 hr prior to sacrifice) alone significantly enchanced only sodium absorption (208.3 versus 147.7 μEq/g/hr in controls). Simultaneous administration of corticosterone and prolactin significantly enchanced both fluid and sodium transport. The data suggest that increased endogenous prolactin levels produce stimulatory effects on intestinal absorption of fluid and NaCl by the rat jejunum.

7704 A COMMON MECHANISM FOR TRANSPORT OF DI- AND TRI-PEPTIDES BY HAMSTER JEJUNUM IN VITRO.

(Eng.) Addison, J. M.; Burston, D.; Dalrymple, J. A.; Matthews, D. M.; Payne, J. W.; Sleisenger, M. H.; Wilkinson, S. (Westminster Medical Sch., London, England). *Clin. Sci. Mol. Med.* 49(4):313-322; 1975.

Transport interactions between amino acids, dipeptides, and tripeptides were studied in rings of everted hamster jejunum *in vitro.* Paired rings were incubated in Krebs-Ringer phosphate saline, each control ring accompanied by a test ring from an adjacent jejunal site of the same hamster. The effects of a variety of amino acids and peptides on the uptake of glycylsarcosylsarcosine (Gly-Sar-Sar) and of β-alanylglycylglycine (β-Ala-Gly-Gly) were studied. The uptake of Gly-Sar-Sar was not inhibited by methionine (Met) or by glycine (Gly), except at the high concentration of 60 μmol/ml. Its uptake was inhibited to 80% and 11% of the control values by 5 and 20 μmol/ml of Met-Met, resp.; to 53% and 13% of the control values by 5 and 20 μmol/ml of Gly-Gly; and to 53% and 23% of the control values by 5 and 20 μmol/ml of Gly-Gly-Gly, resp. Inhibition by Met-Met-Met (5 μmol/ml) was stronger (to 55% of control) than by equimolar Met-Met. *N*-acetyl-Gly-Gly (20 μmol/ml) inhibited the uptake to 83% of the control. Neither equimolar β-Ala nor equimolar histidine (His) affected Gly-Sar-Sar uptake. β-Ala-His (5 and 20 μmol/ml) inhibited uptake of Gly-Sar-Sar (69% and 39%, resp.). His-β-Ala (20 μmol/ml) inhibited uptake to 59% of the control. Gly-Sar-Sar uptake was inhibited to 68% of control by β-Ala-Gly-Gly (20 μmol/ml). Both Gly-Pro and Pro-Gly inhibited uptake of Gly-Sar-Sar, Gly-Pro much more strongly than Pro-Gly. Uptake was inhibited by Gly-Leu, and less strongly by Gly-D-Leu. Uptake was also inhibited to 44% of control by cephalexin (20 μmol/ml). Uptake of Gly-Sar-Sar was unaffected by 5 μmol/ml lysine (Lys) or Lys-Lys-Lys, but was inhibited to 58% of control by 5 μmol/ml Lys-Lys. Uptake was unaffected by 5 or 20 μmol glutamine (Glu) or Glu-Glu, whereas it was inhibited to 70% of control by 5 μmol/ml Glu-Glu-Glu. The results demonstrate that jejunal uptake of tripeptides is inhibited by dipeptides, which suggests that di- and tripeptides share an uptake mechanism. The inhibi-

on of uptake of Gly-Sar-Sar by β-Ala-Gly-Gly and
e inhibition of uptake of β-Ala-Gly-Gly by Gly-
r-Sar also suggest that tripeptides compete
ong themselves for uptake.

'05 THE EFFECT OF SALINE AND HYPERONCOTIC DEXTRAN INFUSION ON CANINE ILEAL SALT AND TER ABSORPTION AND REGIONAL BLOOD FLOW. (Eng.)

ilman, D.; Jordan, K. (Biology Dept., Univ. Hous-
n, Houston, TX 77004). *J. Physiol. (Lond.)*
2(1):97-113; 1975.

e unidirectional Na and H_2O fluxes, vascular pres-
ires, and total and absorptive site blood flows in
e canine ileum were determined before and during
v. saline infusion (9 g/l) and subsequent i.v.
fusion of 25% hyperoncotic dextran (77,000 molecu-
r weight). Continuous saline infusion in-
eased the unidirectional flux of Na and H_2O into
e ileal lumen and increased total blood flow (246%)
d venous pressure (67%). The net absorption of Na
d H_2O was decreased, primarily because of the in-
eased blood-to-lumen fluxes of Na and H_2O by 270%
d 38%, resp. After 150 min, the net control period,
absorption from saline at 0.82 μEq/g/min was con-
rted to a net secretion of 0.78 μEq/g/min. The
idirectional fluxes of Na and H_2O out of the lumen,
terial pressure, and the absorptive site blood flow
re not affected. Dextran infusion reversed most
the effects of saline infusion. There were no
gnificant effects of dextran on the net flux of Na
H_2O, the absorptive flux of Na, or total intesti-
l blood flow. The secretory fluxes of H_2O and the
sorptive site blood flow for the saline-perfused
gments were significantly decreased, but both ar-
rial and mesenteric vein pressures were signifi-
antly increased. The unidirectional fluxes of Na
d H_2O into the lumen were correlated significantly
ith Starling forces during saline infusion. It is
ncluded that intestinal transport of Na and H_2O
s subject to regulation by physical forces at the
apillary level.

706 DEMONSTRATION OF HYDROLASE-RELATED GLUCOSE TRANSPORT IN BRUSH BORDER MEMBRANE VESICLES REPARED FROM GUINEA PIG SMALL INTESTINE. (Eng.)

amaswamy, K.; Malathi, P.; Crane, R. K. (Dept.
hysiology, Coll. Medicine and Dentistry New Jersey,
ewark, NJ). *Biochem. Biophys. Res. Commun.* 68(1):
62-168; 1976.

he transport of glucose, derived from either sucrose
r glucose-1-phosphate (G-1-P), across osmotically
ctive brush border membrane vesicles from guinea
ig small intestine was studied to demonstrate hy-
rolase-related glucose transport. An imposed Na^+
radient enhanced the entry of glucose into the ves-
cles, and the dissipation of the sodium gradient with
ime coincided with the equilibration of glucose across
he vesicular membrane. When glucose uptake was
ompared with that of labeled sucrose, 72-81% of the
adioactivity associated with the vesicles was due to
glucose and the rest was unhydrolyzed sucrose. When the vesicles were incubated with sucrose and tromethamine, a strong competitive inhibitor of sucrase. total uptake was reduced to less than 40%, and the proportions of glucose and sucrose were reversed, demonstrating that unhydrolyzed disaccharide can occupy some portion of the vesicular space. Transport from 10 mM sucrose was compared to that from 1 and 10 mM G-1-P. The amount of glucose released from 10 mM sucrose at the end of 1 min was comparable to that released from 1 mM G-1-P at 40 sec and from 10 mM G-1-P at 20 sec. Comparing vesicular uptake in the presence of Na^+, the uptake from sucrose was 4.7 and 2.9 times greater than that from 1 mM and 10 mM G-1-P, resp. In the absence of Na^+, the corresponding values were 9.4 and 5.3. Even when the amount of glucose released was 3-fold greater from G-1-P (10 mM G-1-P at 1 min), the uptake of glucose from sucrose (10 mM at 1 min) predominated, being 1.5 times greater in the presence of Na^+ and 2.3 times greater in its absence. In the absence of sodium, total sugar uptake from 10 mM sucrose was 1,117 pmol/mg protein at the end of 1 min; correcting for intact sucrose entry, it was found that considerably more glucose from sucrose was transferred into the vesicles than that from G-1-P. This demonstrates that glucose transfer is attributable to hydrolase-related transport.

7707 EFFECTS OF FASTING AND SEMISTARVATION ON THE KINETICS OF ACTIVE AND PASSIVE SUGAR ABSORPTION ACROSS THE SMALL INTESTINE IN VIVO. (Eng.)

Debnam, E. S.; Levin, R. J. (Dept. Physiology, Royal Free Hosp. Sch. Medicine, Hunter St., London, WC1N 1BP, England). *J. Physiol. (Lond.)* 252(3):681-700; 1975.

The effects of fasting and semistarvation on the kinetics of absorption *in vivo* of glucose, galactose, and α-methyl glucoside were assessed electrically and chemically in the jejunum of male albino Sheffield rats and male Golden hamsters. The apparent K_m, maximum absorption (V_{max}, μmol/10 cm/15 min), and maximum potential difference (PD_{max}) were obtained for the jejunal electrogenic active-transfer mechanism from the transfer PD and chemical absorption data. Fasting for 3 days decreased the K_m markedly for all the sugars, but not for L-valine or L-methionine. Semistarvation had a less pronounced effect on the sugars. The diet-induced change in K_m for glucose was observed in both rats and hamsters. These effects may result from the increased affinity of the carriers for sugars during dietary restriction. The greater the restriction, the greater the increase. Fasting and semistarvation caused large reductions in V_{max}. These values were correlated with the reduction in enterocyte population, as estimated by changes in enterocyte column size. The reduction in V_{max} for galactose was mainly accounted for by a decrease in enterocytes; however, these two factors did not correlate for glucose. There were much greater reductions in V_{max} compared to column size. Reduced enterocyte metabolism or changes in the carriers may also be involved. Fasting and semistarvation had complex and differential actions on the PD_{max} for glucose. galactose, and α-methyl glucoside. They did not correlate with the changes in V_{max} measured chemically.

7708 SOME OBSERVATIONS ON THE POSSIBLE NUTRITIONAL SIGNIFICANCE OF VITAMIN B_{12}- AND FOLATE-BINDING PROTEINS IN MILK. ABSORPTION OF [^{58}Co]CYANOCOBALAMIN BY SUCKLING PIGLETS. (Eng.) Ford, J. E.; Scott, K. J.; Sansom, B. F.; Taylor, P. J. (National Inst. for Research in Dairying, Shinfield, Reading RG2 9AT, England). *Br. J. Nutr.* 34(3):469-492; 1975.

The absorption and retention of ^{58}Co-cyanocobalamin (CCB) and its partition within the body were investigated in Large White piglets at birth or at ages up to 56 days. CCB given at birth and at 7 days of age by stomach tube was efficiently absorbed from the intestine and retained within the body, mostly in the liver. Test doses of 10 and 0.5 μg were absorbed equally well, despite the absence of intrinsic factor in the gut. In piglets given 10 μg at ages between 0.5 and 56 days, the retention efficiency decreased markedly between about 7 and 21 days of age. Total liver vitamin B_{12} increased progressively from 4.2 μg at birth to 53.7 μg at 63 days. Liver folate content increased from 6.3 μg at birth to 242 μg at 35 days, after which it accelerated sharply (to 2,555 μg at 56 days). Vitamin B_{12}-binding capacity in the gastric mucosa increased with age, from 40 ng at birth to about 2,000 ng at 14 days and 7,000 ng at 35 days. This binder protein was largely endogenous, but much of the unsaturated binder protein in intestinal mucosa was apparently derived from milk. The chyme in the stomach and small intestine contained unsaturated binder protein, partly endogenous and partly derived from milk, which prevented uptake of added G-^{3}H-CCB into the solid phase of the intestinal contents. The intestinal chyme contained large numbers ($\log_{10}$ 7.0-9.1/ml) of bacteria, some of which were isolated and shown to take up CCB or folic acid or both. It is speculated that unsaturated vitamin binders in milk, in acting to sequester the milk folate and reduce the growth of folate-dependent bacteria in the intestine, would encourage the growth of bacteria that contribute to the host's folate nutrition.

7709 AN INVESTIGATION OF THE MECHANISMS RESPONSIBLE FOR A REDUCTION IN CAPILLARY FILTRATION COEFFICIENT IN THE INNERVATED CAT JEJUNUM ON INTRAVENOUS INFUSION OF HISTAMINE. (Eng.) Richardson, P. D. I. MOTILITY

22 THE ADRENO-MEDULLARY EFFECT ON GASTROINTESTINAL PROPULSION AFTER LAPAROTOMY. EXPERIMENTAL STUDY IN THE RAT. (Eng.) Ohrn, -G.; Johansson, H.; Nilsson, F. (Univ. Hosp., S-750 Uppsala, Sweden). *Acta Chir. Scand.* 142(Suppl. 1);19-29; 1976.

e effects of adrenalectomy and adrenal demedul- tion on the rates of gastric evacuation and all intestinal propulsion following laparotomy re investigated in male Sprague-Dawley rats. am-operated controls, in which the adrenals were rely exposed, were also studied. Laparotomy was rformed 7 days after adrenal or sham surgery, and strointestinal propulsion was studied 15 hr ter laparotomy. None of the procedures induced gnificant body weight alterations; serum electro- tes were unaffected by adrenalectomy. After renalectomy and adrenal demedullation, the corti- steroid plasma levels were significantly reduced, e concentrations after total adrenalectomy being e lowest. Laparotomy did not affect the plasma rticosteroid levels. Gastric evacuation was gnificantly increased in nonlaparotomized animals bjected to adrenalectomy ($p<0.001$) and adrenal emedullation ($p<0.05$) compared to nonlaparotomized am-operated controls. Laparotomy significantly etarded gastric evacuation in the sham-operated roup ($p<0.001$), but did not alter gastric evacua- ion in the adrenalectomized and adrenal demedullated roups. Small bowel propulsion did not differ etween nonlaparotomized rats subjected to adrena- ectomy, adrenal demedullation, or sham operation. e propulsion was significantly retarded ($p<0.01$) n the laparotomized sham-operated animals, but as unaffected in the laparotomized adrenalectomized nd adrenal demedullated animals. It is concluded hat adreno-medullary activity retards gastro- ntestinal propulsion, not only postoperatively, ut also in intact rats.

723 EFFECT OF CHEMICAL SYMPATHECTOMY (6-HYDROXYDOPAMINE) ON GASTROINTESTINAL PROPULSION FTER LAPAROTOMY: AN EXPERIMENTAL STUDY IN THE RAT. (Eng.) Ohrin, P.-G.; Rentzhog, L. (Univ. Hosp., S-750 14 Uppsala, Sweden). *Acta Chir. Scand.* 142(Suppl. 461):31-42; 1976.

The effects of 6-hydroxydopamine pretreatment or adrenal demedullation on the inhibition of gastrointestinal propulsion following laparotomy were studied in Sprague-Dawley rats to determine whether the postoperative inhibition is due to the activation of peripheral sympathetic nerves. The animals were pretreated with 6-hydroxydopamine (50 mg/kg at 15 or 48 hr or 150 mg/kg at 48 hr, i.v.) before the evaluation of gastrointestinal propulsion. Treatment with 6-hydroxydopamine did not prevent postoperative retardation of gastric evacuation and small bowel propulsion. On the contrary, 6-hydroxydopamine in itself seemed to retard gastrointestinal propulsion. In simultaneously adrenal demedullated rats, no further retardation of propulsion was produced by the laparotomy. The results indicate that the adreno-medullary discharge is important in the postoperative inhibition of gastrointestinal propulsion.

7724 CATECHOLAMINE INFUSION AND GASTROINTESTINAL PROPULSION IN THE RAT. (Eng.) Ohrn, P.-G. (Univ. Hosp., S-750 14 Uppsala, Sweden). *Acta Chir. Scand.* 142(Suppl. 461):43-52; 1976.

The effects of continuous i.v. infusions of adrenalin (A), noradrenalin (NA), and saline on gastric evacuation and small bowel propulsion were studied in male Sprague-Dawley rats to confirm the inhibitory effect of circulating catecholamines on gastrointestinal propulsion. The rats received 4 μg/ml (2 ml/hr) of noradrenalin or adrenalin, beginning 15 min before the administration of a test meal. The amount of the test meal evacuated from the stomachs of the A-treated, NA-treated, and control rats was 68.6%, 69.8%, and 82.7%, resp. The small bowel length passed by 50% and 25% of the test meal was significantly shorter in the A-treated rats (62.3% and 67.9%, resp.) and in the NA-treated rats (62.8% and 68.5%, resp.) than in the controls (67.5% and 74.5%, resp.). However, there was no difference in small bowel length passed by 75% of the test meal. The results indicate that both gastric evacuation and small bowel propulsion are significantly inhibited by the infusion of catecholamines.

7725 EFFECT OF ADRENERGIC BLOCKADE ON GASTROINTESTINAL PROPULSION AFTER LAPAROTOMY: AN EXPERIMENTAL STUDY IN THE RAT.

(Eng.) Ohrn, P.-G.; Rentzhog, L. (Univ. Hosp., S-750 14 Uppsala, Sweden). *Acta Chir. Scand.* 142(Suppl. 461):53-64; 1976.

The effects of alpha- and beta-adrenergic blockade on the retardation of gastrointestinal propulsion following laparotomy were studied in male Sprague-Dawley rats. Gastric evacuation was reduced 15 hr after laparotomy, only 74.7% of a test meal being evacuated. The intestinal propulsion was calculated as the percentage of small bowel length passed by 75%, 50%, and 25% of the activity deposited into the duodenum; these levels after laparotomy were 57.2%, 64.4%, and 69.2%, resp. Gastric evacuation after laparotomy was significantly improved by alpha blockade with phenoxybenzamine (3 mg/kg, i.v.), the mean gastric evacuation being 92.7%. The gastric evacuation in nonlaparotomized, phenoxybenzamine-treated animals was 92.0%. No differences in small bowel length passed by 75% and 50% of the test meal were found between the groups, irrespective of phenoxybenzamine treatment plus laparotomy, phenoxybenzamine alone, or laparotomy alone. A significantly shorter part of the small bowel was passed by 25% of the test meal in the laparotomized animals not subjected to phenoxybenzamine pretreatment compared to the pretreated laparotomized animals (75.0%). In a second series of experiments, gastric evacuation was significantly reduced in the untreated control group after laparotomy (68.4% of test meal evacuated). Beta blockade with propranolol (5 mg/kg x 2, s.c.) did not prevent the reduction of gastric evacuation after laparotomy. Small bowel propulsion was significantly retarded in untreated controls after laparotomy. There was no significant difference between the laparotomized groups, irrespective of beta-blocking treatment. However, when the small bowel propulsion in the propranolol-treated laparotomized group was compared with that of the corresponding propranolol-treated nonlaparotomized group, no significant difference was found. These studies indicate that the postoperative retardation of gastric evacuation depends mainly on adrenal discharge of catecholamines that directly stimulate inhibitory alpha-receptors in the stomach.

7726 EFFECTS OF SYMPATHO-ADRENAL ACTIVITY AND PHARMACOLOGICAL TREATMENT ON GASTROINTESTINAL PROPULSION IN THE EARLY POSTOPERATIVE PERIOD. AN EXPERIMENTAL STUDY IN THE LAPAROTOMIZED RAT.

(Eng.) Ohrn, P.-G.; Rentzhog, L.; Wikstrom, S. (Univ. Hosp., S-750 14 Uppsala, Sweden). *Acta Chir. Scand.* 142(Suppl. 461):65-76; 1976.

The effects of various sympatho-adrenal manipulations on gastrointestinal propulsion after laparotomy were investigated in male Sprague-Dawley rats. Following laparotomy, there was a significant retardation of gastric evacuation and of small bowel propulsion. Neither adrenal demedullation 7 days before laparotomy nor chemical sympathectomy with 6-hydroxydopamine (150 mg/kg, i.v., 46 hr before operation) had any effect on gastric evacuation after surgery. Gastric evacuation was not affected by treatment with neostigmine (0.1 mg/kg, s.c), phenoxybenzamine (3 mg/kg, i.v.), or metoclopramide (3 mg/kg, s.c.). Chemical sympathectomy abolished the postoperative retardation of small bowel propulsion, and treatment with metoclopramide significantly improved, but did not abolish, retardation. Neostigmine, phenoxybenzamine, and adrenal demedullation did not affect the slowed intestinal propulsion. In 5 of 16 neostigmine-treated animals and in 4 of 16 animals subjected to adrenal demedullation, significant duodenal-gastric reflux was observed after administration of a duodenal test meal. The results indicate that it is difficult to influence the inhibited gastric evacuation therapeutically in the early postoperative period; however, the inhibition of small bowel propulsive motility is less pronounced.

7727 GASTRIC EMPTYING OF LIQUIDS AFTER DIFFERENT VAGOTOMIES AND PYLOROPLASTY.

(Eng.) Gleysteen, J. J.; Burdeshaw, J. A.; Hallenbeck, G. A. (Dept. Surgery, Univ. Alabama, Birmingham, AL). *Surg. Gynecol. Obstet.* 142(1):41-48; 1976.

The relative rate of gastric emptying of liquids (0.1 N sodium citrate, 5% dextrose, 10% dextrose, 0.05 N HCl, and 10 mN sodium oleate buffered in 0.1 N sodium citrate), after different vagotomies and pyloroplasty was determined in 10 mongrel dogs. Measurements wer made during the first brief phase after ingestion and during the second longer exponential phase of emptyin using intact dogs and dogs after a Heinecke-Mikulicz pyloroplasty, proximal gastric vagotomy without drainage, total gastric-selective gastric vagotomy plus pyloroplasty (SG-V-P), and total abdominal-truncal vagotomy plus pyloroplasty (TV-P). Pyloroplasty alon did not change the emptying rate of the liquids. Whe compared across operations, there was a significant difference in emptying among individual meals for bot the initial rate (p<0.0001) and the basic relative rate (p<0.0001). Initial emptying after all three vagotomies was significantly faster than control rates, with progressive rate increases when proximal gastric vagotomy is compared with SGV-P and with TV-P. The basic exponential pattern of emptying was not lost after any of the operations. The basic rate after proximal gastric vagotomy and SGV-P was nearly identical, slightly delayed from the control rate, and significantly slower than the more rapid rate after truncal vagotomy with pyloroplasty. These results imply the importance of the hepatic and celiac vagal fibers, sectioned only with truncal vagotomy, in the regulation of gastric emptying of liquid.

7728 EFFECT OF ISCHEMIC ANOXIA ON ELECTRICAL AND MECHANICAL ACTIVITY OF THE TOTALLY ISOLATED PORCINE STOMACH.

(Eng.) Kowalewski, K.; Zajac, S.; Kolodej, A. (Surgical-Medical Res. Inst., Univ. Alberta, Edmonton, T6G 2H7, Alberta, Canada); *Eur. Surg. Res.* 8(1):12-25; 1976.

The effect of ischemic anoxia on the electrical and mechanical activity of the isolated porcine stomach perfused with homologous blood was investigated. Stagnant, complete ischemia was produced by closing the gastric artery and vein for various periods of time up to 3 hr. After a given period of ischemia, the blood was recirculated for 10 min and then pentagastrin (5 µg/ml/min) was injected into the gastric artery. The vagus nerve was also electrically stimulated at various stages of anoxia and recirculation. After up to 90 min of ischemia, stomachs were able to demonstrate low-frequency electrical control activity after 10 min of blood recirculation. After injection of pentagastrin, however, electrical control activity rapidly became normal. When ischemia lasted 120 min or longer, recirculation of blood did not induce reappearance of electrical control activity, but again pentagastrin injection produced a normal response. After ischemia of 240 min duration or longer, recirculation and pentagastrin had no effect. This experimental study may have some clinical significance, as normothermic stagnant ischemia of a few hours' duration does occur under clinical conditions.

7729 THE EFFECTS OF SOME PHARMACOLOGICALLY ACTIVE AMINES ON THE RATE OF GASTRIC EMPTYING IN RATS. (Eng.) Bridges, J. W.; Dent, J. G.; Johnson, P. (Univ. Surrey, Guildford, England). *Life Sci.* 18(1): 97-107; 1976.

The effects of some pharmacologically active anticholinergic and nonanticholinergic amines on the rate of gastric emptying were studied in Wistar rats. All compounds were administered by gastric intubation at 0.2 mmol/kg. In one series of experiments, the test compound and polyethylene (1,2-^{14}C)-glycol (^{14}C-PEG, 5 mg) were administered together or ^{14}C-PEG was administered 45 min after the test compound. Compounds with anticholinergic activity (amitriptyline, nortriptyline, imipramine, desmethylimipramine, 3-methylamino-1:1-diphenyl-prop-1-ene and its primary and tertiary amine analogues, dexamphetamine and methylamphetamine) all inhibited gastric emptying of PEG. The mean percentage of marker retained in the controls was 0.4, while the percentages retained in the animals treated with the anticholinergic compounds were 14.1%, 36.0% ($p>0.001$), 24.3% ($0.1>p>0.001$), 39.0% ($0.1>p>0.001$), 11.8%, 9.2% ($0.05>p>0.01$), and 15.6%, resp. Compounds with little or no anticholinergic activity (phenobarbitone, piperazine, oxyphenylbutazone, and trimethoprim) had no effect on gastric emptying. The activity of the compounds in inhibiting gastric emptying falls in approximately the same order as their anticholinergic activity, lending support to the hypothesis that inhibition of gastric emptying is via an anticholinergic mechanism. The results also indicate that absorption is a prerequisite of activity in inhibiting gastric emptying and suggest that these compounds are not acting via a local mechanism.

7730 EFFECTS OF ANTACIDS ON GASTRIC EMPTYING. (Eng.) Hurwitz, A.; Robinson, R. G.; Vats, T. S.; Whittier, F. C.; Herrin, W. F. (Univ. Kansas Medical Center, 39th and Rainbow Streets, Kansas City, KS 66103). *Gastroenterology* 71(2):268-273; 1976.

The effect of antacids on gastric emptying was studied in male Sprague-Dawley rats and in eight children, and the characteristics of the antacids that determine their effect on this function were investigated. The rats were given three 0.5-ml doses of water, antacid (aluminum hydroxide gel), or solutions of sodium, magnesium, or aluminum chloride by gastric intubation at 1-hr intervals. Immediately after the third dose, the animals were given 0.5 ml of either polyethylene glycol 4000 (PEG) 4%, phenol red 0.5%, or water. Twenty minutes after the third dose of aluminum hydroxide gel, the volume of gastric contents was nearly 5 times greater than that of controls, whereas an antacid containing magnesium trisilicate in addition to aluminum hydroxide had no effect on gastric fluid retention in rat stomachs. When over 80% of the PEG had left the stomachs of controls, less than 40% of this marker had left the stomachs of animals given aluminum hydroxide gel, demonstrating that the increased fluid volume in the aluminum hydroxide-treated rats was due to delayed gastric emptying and not just to increased gastric secretion. The stomachs of the animals receiving aluminum hydroxide gel had a more than 20-fold greater concentration of aluminum than did those of either water or combination antacid-treated animals. When the pH, osmolality, aluminum concentration, and anion composition were carefully controlled, the delay in gastric emptying was found to depend only on the aluminum concentration, whereas magnesium did not affect the ability of aluminum to slow gastric emptying. By using ^{51}Cr-sodium chromate and a gamma camera technique, the half-emptying time in six human subjects with no gastrointestinal disease was shown to be prolonged from 13.1 min after water ingestion to 48.0 min after three hourly doses of aluminum hydroxide gel (4 ml/10 pounds, not exceeding 45 ml, for each interval). Conventional nonabsorbable markers, including phenol red, were found to be of limited use for studying gastrointestinal function in the presence of antacid gels, most of which absorb dyes. The results suggest that because aluminum hydroxide gel delays gastric emptying, it should not be used in patients with partial gastric outlet obstruction. However, a desirable property of aluminum hydroxide gel may be its protracted, although incomplete, neutralization of gastric content.

7731 EFFECTS OF NICOTINE ON REBOUND EXCITATION OF GUINEA-PIG SMALL INTESTINE. (Eng.) Wood, J. D.; Rose, B. A.; Jackson, M. H. (Univ. Kansas Medical Center, Kansas City, KN 66103). *J. Pharmacol. Exp. Ther.* 196(1):71-79; 1976.

Experiments were carried out in guinea pig small intestinal segments to confirm the presence of muscarinic receptors on intrinsic inhibitory intestinal neurons. The suggestion that potentiation of the poststimulus response by atropine results from the blockade of muscarinic receptors on intrinsic inhibitory neurons was also tested. Poststimulus rebound contractions and associated action potentials of the circular muscle layer occurred after termination of transmural electrical stimulation. Low concentrations of nicotine (1-5 x 10^{-6} g/ml) either abolished or greatly reduced the poststimulus response. The contractile force and time duration of the response were reduced, and the latency of the response was increased by low concentrations of nicotine. The depressant action of nicotine was reversed by an increase in concentration from 5 x 10^{-6} g/ml. The effects of low concentrations of nicotine were mimicked by 1,1-dimethyl-4-phenylpiperazinium iodide (1 x 10^{-6}, 5 x 10^{-6}, and 1 x 10^{-5} g/ml), and they were prevented by hexamethonium (1 x 10^{-4} g/ml), pentolinium (5 x 10^{-5} g/ml), gallamine (1 x 10^{-5}, 2.5 x 10^{-5}, 5 x 10^{-5}, and 7.5 x 10^{-5} g/ml), and large concentrations of atropine (1 x 10^{-5} g/ml atropine, 1 x 10^{-4} g/ml nicotine). Gallamine increased myogenic electrical and mechanical activity and potentiated the poststimulus rebound response. Pretreatment with guanethidine produced a small reduction in the inhibitory action of nicotine. Propranolol (5 x 10^{-7} to 5 x 10^{-6} g/ml) and phentolamine (5 x 10^{-7} to 1 x 10^{-5} g/ml) suppressed the poststimulus response, but the specificity of the action was questionable. The effects of nicotine may be mediated by excitation of the intrinsic inhibitory neurons.

7732 MECHANISMS OF THE CONTRACTING ACTION OF K, ACETYLCHOLINE AND Ba AND OF THE ANTISPASMODIC ACTION OF Cd AND Mn ON THE PYLORIC ANTRUM STRIP OF RAT STOMACH, PARTICULARLY IN RELATION TO Ca. (Jpn.) Shino, H. (Kobe Univ. Sch. Medicine, Ikuta-ku, Kobe 650, Japan). *Folia Pharmacol. Jpn.* 72(1): 95-104; 1976.

7733 MECHANISMS OF THE CONTRACTING ACTION OF K, ACETYLCHOLINE AND Ba ON THE ISOLATED RAT RECTUM, ESPECIALLY IN RELATION TO Ca. (Jpn.) Taniyama, K.; Araki, H.; Maeda, M.; Cheng, J.-T.; Matsumoto, H. (Kobe Univ. Sch. Medicine, Ikuta-ku, Kobe 650, Japan). *Folia Pharmacol. Jpn.* 72(1):105-111; 1976.

SECRETION AND METABOLISM

7735 SIMULTANEOUS RADIOIMMUNOASSAY OF SECRETIN AND GASTRIN. (Eng.) Tai, H.-H.; Chey, W. Y. (Isaac Gordon Center Gastroenterology, Genesee Hosp., 224 Alexander St., Rochester, NY 14607). *Anal. Biochem.* 74(1):12-24; 1976.

Radioimmunoassay techniques for the measurement of secretin and gastrin have been modified by using highly specific antisera and labeled hormones of different isotopes (^{125}I-labeled secretin and ^{131}I-labeled gastrin) to allow simultaneous measurement of both hormones in the same plasma samples. Less than 0.01% cross reactivity was observed with either antibody against the other hormone. Preincubation of the antibodies for 24 hr with unlabeled hormones greatly increased the sensitivity of the assay. The plasma- and dextran-coated charcoal effectively separated the free from the bound form of both hormones. The presence of 150 mM sodium chloride, 100 mM urea, 10 mM creatinine, 10 mM glucose, and 25 U/ml heparin did not affect the separation procedure. Linearity of the assay was demonstrated, and the coefficients of variation were 6.1-7.4% for secretin and 3.7-4.3% for gastrin. The concentrations of the two hormones were determined in 44 fasting normal human subjects. The mean secretin concentration was 62.9 pg/ml (range, 19.5-139.7), while that for gastrin was 43.5 pg/ml (range, 22.3-109.1). Thus, simultaneous radioimmunoassay of secretin and gastrin may be performed without loss of sensitivity, specificity, and precision of the individual assays.

7736 THE INFLUENCE OF COFFEE AND CAFFEINE ON SERUM GASTRIN AND ACID SECRETION IN MAN. (Ger.) Borger, H. W.; Schafmayer, A.; Arnold, R.; Becker, H. D.; Creutzfeldt, W. (Klinik fur Allgemeinchirurgie der Universitat, 3400 Gottingen, Gosslerstr. 10, W. Germany). *Dtsch. Med. Wochenschr.* 101(12):455-457; 1976.

The effect of coffee, caffeine, and decaffeinated coffee on serum gastrin levels and acid secretion was determined in five healthy volunteers. Serum samples were drawn every 15 min for 3 hr after ingestion, and aspirated specimens of gastric juice were taken every 10 min for 1.5 hr following gavage of the test agents. Gastric acidity increased negligibly after caffeine, but increased significantly ($p<0.05$) after decaffeinated coffee and cofee during the first 90 min. At 90-150 min, the ncrease in acidity over a water standard was 1.9, .6, and 6.6 mmol/hr for caffeine, coffee, and lecaffeinated coffee, resp., all of which were significant ($p<0.05$). Serum gastrin rose from a basal 28 ng/l to 54 ng/l after coffee and from 27 g/l to 60 ng/l after decaffeinated coffee, both of which are significant ($p<0.05$). It is suggested that gastrin liberation might be attributable to ingredients unique to the coffee roasting process.

7737 EFFECT OF JEJUNAL RESECTION ON THE GASTRIC ACID SECRETORY RESPONSE TO PENTAGASTRIN, HISTAMINE AND FEEDING IN DOGS. (Eng.) Brihaye, C.; Noussen-Colle, M. C.; Limbosch, J. M.; de Graef, J. (Hopital Saint-Pierre, 322 rue Haute, B-1000 Brussels, Belgium). *Digestion* 14(2):153-162; 1976.

The effect of resection of the upper half of the small intestine on the acid secretory responses to a meal and to graded doses of histamine and pentagastrin was investigated in dogs with gastric fistulas and vagally denervated Heidenhain pouches of the oxyntic gland area. In the gastric fistula, no changes in the dose-response curves for histamine or pentagastrin were observed after resection of the upper small intestine. In the Heidenhain pouch, jejunectomy resulted in an increase of the responses to both histamine (20% increase) and pentagastrin (44% increase). The ED$_{50}$ values did not change significantly. After bowel resection, the Heidenhain pouch maximal acid response to feeding was increased by 68%, and the total response was increased by 92%. The secretory response was more prolonged after the operation. The data indicate that both an increase in stimulation and an increase of the response to this stimulation are responsible for the increased acid secretion observed in the pouch when resected dogs were fed. The effects could be explained by the withdrawal of inhibitors originating in the intestine.

7738 SERUM GASTRIN LEVEL IN EARLY CHILDHOOD. (Eng.) Sann, L.; Chayvialle, J. A. P.; Bremond, A.; Lambert, R. (INSERM U-45, Pavillon H vis, Hopital Edouard-Herriot, 69374 Lyon, France). *Arch. Dis. Child.* 50(10):782-785; 1975.

SECRETION AND METABOLISM

Stomach

7745 STUDIES ON THE MECHANISMS OF FOOD-STIMULATED GASTRIC ACID SECRETION IN NORMAL HUMAN SUBJECTS. (Eng.) Richardson, C. T.; Walsh, J. H.; Hicks, M. I.; Fordtran, J. S. (Univ. Texas Health Science Center, Dallas, TX 75235). *J. Clin. Invest.* 58(3):623-631; 1976.

Gastric acid secretion after infusion of a variety of liquid meals was studied in 19 normal adult subjects by intragastric titration at pH 5.0. Secretion after 500 or 750 ml of a 0.643% NaCl meal was 2-3 times higher than the basal secretion rate ($p<0.02$), and amounted to 25-30% of the peak secretory response to histamine (0.04 mg/kg). Neither of the NaCl meals caused an increase in the basal serum level of gastrin. A 500-ml glucose meal (14 g glucose + 120 g cornstarch) caused a similar increase in acid secretion and a small, but definite, increase in serum gastrin during the first 30 min after the meal. A 500-ml amino acid (casein hydrolysate) meal caused a greater acid secretory response than the other meals (50% of the peak histamine stimulation), as well as a greater gastrin response than the other meals. The NaCl and amino acids meals were almost completely emptied from the stomach by the end of the 2-hr observation period, but 16% of the polyethylene glycol in the glucose meal was still in the stomach after 2 hr, and the gastric volume was greater than with the other meals. The addition of fat (40 g Lipomul) to a glucose meal inhibited the acid secretory response in 2 hr from 15.6 to 12.0 mEq ($p<0.05$), but increased the integrated gastrin response from 0.51 to 2.18 ng/min/ml ($p<0.05$). Addition of 20 g of amino acids to the carbohydrate-fat meal increased acid secretion to 42% of the peak response to histamine, but 20 g of albumin did not further stimulate acid secretion. The addition of amino acids (20 g) to the carbohydrate-fat meal also increased the gastrin response significantly. There was a close correlation between the mean integrated gastrin response and the mean rate of acid secretion ($r=0.97$), but there was a poor correlation between acid secretion and serum gastrin concentration when the responses of the individual subjects with a given test meal were compared. It is concluded that distention is an important stimulant of the acid secretory response to a meal, and that this is not mediated by gastrin release. Since the acid secretion noted with amino acids cannot be explained by distention, it is likely that gastrin is not the only mediator of the chemical phase of acid secretion. The rise in serum gastrin after glucose was too small and too transient to enhance acid secretion. Fat probably releases unmeasured inhibitors that overwhelm the effect of gastrin on acid secretion.

7746 STUDIES ON THE ACID SECRETION THAT OCCURS DURING INJURY TO THE GASTRIC MUCOSA.

(Eng.) Thompson, M. R. (The Royal Infirmary, Oxford Road, Manchester, MI3 9WL, England). *Gastroenterology* 71 (2):286-290; 1976.

Gastric acid secretion was studied in pouches of the oxyntic glandular mucosa in dogs after irrigation of the pouches with 4 mM dithiothreitol (DTT) in acid solution to cause injury. Instillation of DTT resulted in a large efflux of sodium into the pouch, accompanied by a large increase in volume output, part of which was plasma. This was interpreted as indicating a marked increase in the permeability of the mucosa to sodium and plasma. In spite of this, there was a net addition of acid to the pouch, amounting to nearly 1,200 μEq/30 min. Atropine (0.1 mg/kg, i.v.), metiamide (2.9-11.6 mg/kg, i.v.), or prostaglandin E_2 (PGE_2, 0.015-0.06 μg/kg/min, i.v.) significantly reduced the net addition of H^+ to the pouch, probably by reducing acid secretion. Increased back-diffusion was considered unlikely to explain the reduction in increase in net H^+ concentration in the pouch. All three drugs also significantly reduced the volume and plasma output induced by DTT. In this respect, PGE_2 was the most effective, and atropine was the least effective. There was a linear correlation ($r=0.92$) between the plasma output and the net H^+ flux during the control, metiamide, and PGE_2 experiments. All three drugs also caused a significant reduction in sodium efflux, which had a linear correlation ($r=0.95$) with plasma output. It is suggested that the mechanisms of acid secretion and plasma shedding are closely related, and that the three drugs used may be useful in the management of protein-losing gastropathy in man.

7747 INTERACTION OF ^{3}H-LABELLED SYNTHETIC HUMAN GASTRIN WITH RAT GASTRIC PLASMA MEMBRANES. EVIDENCE FOR THE EXISTENCE OF BIOLOGICALLY REACTIVE GASTRIN RECEPTOR SITES.

(Eng.) Lewin, M.; Soumarmon, A.; Bali, J. P.; Bonfils, S.; Girma, J. P.; Morgat, J. L.; Fromageot, P. (Unite de Recherches de Gastroenterologie, INSERM U-10, Hopital Bichat, 75877 Paris, Cedex 18, France). *FEBS Lett.* 66(2): 168-172; 1976.

Preliminary results of the binding of ^{3}H-synthetic human gastrin I (^{3}H-GI) to the gastric plasma membranes (GPM) purified from the fundic mucosa of male Wistar rats are reported. The GPM was prepared by sucrose gradient centrifugation. The preparation was relatively free of mitochondria and rough reticulum, as demonstrated by the content of marker enzymes. Electron microscopy of the band (1.12-1.14 g/cm^3) revealed smooth surface vesicles with a mean diameter of 1 μm and additional unclosed membrane fragments. The time course of association of ^{3}H-GI and GPM was roughly exponential, and equilibrium was achieved within 8 min, at which time 1-5% of the total radioactivity was bound per milligram of protein. The association constant was 4.2 x 10^{-7} M/min. Binding was reversible upon dilution of the incubation medium, and the half-time for dissociation was 2 min. ^{3}H-GI and unlabeled synthetic human gastrin I competed for binding, and equilibrium values for a given concentration of ^{3}H-GI were proportional to membrane protein concentration. Scatchard plot analysis indicated $N=42 \times 10^{-14}$ mol/mg of membrane protein and $K=1.7 \times 10^{-8}$ M. The basal adenyl cyclase activity in the GPM was enriched twofold over the homogenate, and this activity was stimulated by the presence of 10^{-8} M ^{3}H-GI, suggesting the involvement of 3',5'-AMP in the regulation of gastric acid secretion in the rat.

7748 DEGRADATION OF GASTRIN BY GASTRIC MUCOSAL CELLS.

(Eng.) Del Mazo, J.; McGuigan, J. E. (Univ. Florida Coll. Medicine, Gainesville, FL 32610). *J. Lab. Clin. Med.* 88(2):292-300; 1976.

Studies relating to the binding of ^{125}I-labeled synthetic human gastrin I heptadecapeptide (gastrin) by guinea pig gastric mucosal cells are reported. The cell binding of gastrin was not significantly affected by the presence of either insulin or glucagon, but it was reduced in the presence of nonlabeled

astrin hexadecapeptide. Maximum specific binding
f gastrin occurred at pH 7.4 and at 4 C. The as-
ociation constant of the binding was calculated to
e 5.0 x 10^{-9} M. Damage to gastrin following incuba-
ion with gastric mucosa cells was determined by
pecific antibody binding and was found to be greatest
ith gastrin-mucosal cell incubations at pH 7.4 and
t pH 2.0, with reductions in antibody binding of
0 and 15.2%, resp. No damage was detected at pH
.0, and the presence of at least two gastrin-degrad-
ng enzyme systems is suggested. After incubation at
H 7.4 at 4 C for 30 min, the ability to bind to
resh mucosal cells during a second subsequent incu-
ation was lost. There was no change in the chro-
atographic characteristics of gastrin preincubated
ith mucosal cells, even though antibody binding was
artially lost and binding ability to fresh mucosal
ells was completely lost. The inclusion of trasylol
1,000 U/ml) did not alter the binding of gastrin to
ucosal cells.

749 THE EFFECT OF METIAMIDE ON ACID SECRETION
STIMULATED BY GASTRIN, ACETYLCHOLINE, AND
IBUTYRYL CYCLIC ADENOSINE 3',5'-MONOPHOSPHATE IN
HE ISOLATED WHOLE STOMACH OF THE RAT. (Eng.)
unce, K. T.; Parsons, M. E.; Rollings, N. A. (Res.
nst., Smith Kline & French Lab., Ltd., Welwyn
arden City, Hertfordshire, England). *Br. J. Phar-*
acol. 58(1):149-156; 1976.

he effect of metiamide on the stimulation of gastric
cid secretion by gastrin, acetylcholine, and di-
utyryl cyclic adenosine 3',5'-monophosphate (DBcAMP)
as investigated using an isolated stomach prepara-
ion for immature rats. The hydrogen ion concentra-
ion was measured continuously in the perfusate of
he stomach lumen. Dose-response curves were deter-
ined for all three stimulants. The threshold con-
entration for gastrin was 10^{-8} M, and the response
as linear over the range of 3 x 10^{-8} M to 3 x 10^{-7}
. Metiamide (10^{-5}-3 x 10^{-5} M) effectively inhibited
astrin-stimulated acid secretion. The threshold
oncentration for acetylcholine was 10^{-4} M, and the
esponse was linear over the range of 3 x 10^{-4} M to
0^{-3} M. Concentrations above 3 x 10^{-3} M diminished
he basal rate of acid secretion. The threshold
oncentration for DBcAMP was 5 x 10^{-6} M. The dose-
esponse curve was constructed over the range of 5
10^{-5} M and 1.5 x 10^{-4} M. Metiamide did not inhibit
he acid secretion stimulated by either acetylcholine
r DBcAMP. The rat isolated stomach preparation is
useful tool for the elucidation of the control of
astric function. The failure of metiamide to in-
ibit DBcAMP-stimulated acid secretion supports the
onclusion that cyclic AMP operates at a position
istal to histamine in the chain of events leading to
cid secretion.

750 A QUANTITATIVE STUDY OF METIAMIDE, A HIS-
TAMINE H_2-ANTAGONIST, ON THE ISOLATED WHOLE
AT STOMACH. (Eng.) Bunce, K. T.; Parsons, M. E.
Research Inst., Smith Kline and French Labs., Ltd.,
elwyn Garden City, Hertfordshire, England). *J. Phy-*
iol. (Lond.) 258(2):453-465; 1976.

he inhibition of acid secretion by metiamide was studied quantitatively in the isolated perfused whole rat stomach. Dose-response curves to histamine in the presence and absence of metiamide were constructed. The mean basal acid secretion before stimulation was 4.19 x 10^{-8} mol/min. Metiamide (3 x 10^{-6}, 10^{-5}, and 3 x 10^{-5} M) did not reduce this amount significantly. With histamine-stimulated (10^{-5}-10^{-4} M) acid secretion, however, all three doses of metiamide caused a parallel and significant displacement of the histamine dose-response curves, indicating competitive antagonism. Dose ratios were determined from the dose-response curves; a plot of $\log_{10}$(DR-1) against $\log_{10}$[metiamide] gave a pA_2 value for metiamide of 5.91. The isolated perfused rat stomach is concluded to be useful for the quantitative investigation of gastric secretion.

7751 DOSE-EFFECT RELATIONSHIPS FOR REPEATED INJECTIONS OF PENTAGASTRIN IN RAT STOMACH INNERVATED BY THE VAGUS NERVE IN PERFUSION TESTS. (Ger.) de Boer, A.; Hantschmann, N. (Chirurgische Universitatsklinik Kiel, BRD, 23 Kiel, Hospitalstrasse 40, W. Germany). *Z. Exp. Chir.* 8(6):343-349; 1975.

The dose-response relation of pentagastrin to gastric secretion before and after vagal section is analyzed. Male Wistar rats anesthetized by urethane i.p. or s.c. received two s.c. injections of pentagastrin (PG) at 150-min intervals in 5-, 10-, 15-, 20-, 25-, and 30-μg/100 g doses, and the total acid secretion was measured. The 5-μg dose elicited an increase in acid secretion from 2.6 to 9.8 μEq at 40 min postinjection, which normalized at 140 min. The second injection led to the same maximum after only 20-30 min. An identical pattern was followed for subsequent dose level after the first and second PG injections, resp.: at 10 μg, 12.9 μEq and 10.4 μEq; at 15 μg, 15.4 μEq and 16.2 μEq; at 20 μg, 17.9 μEq and 18.5 μEq; at 25 μg, 15.5 μEq and 13.7 μEq; and at 30 μg, 17.0 μEq and 16.18 μEq. Doses higher than 20 μg/100 g harvested proportionally less acid, suggesting an inhibitory mechanism released by elevated gastrin levels. This phenomenon occurs also after truncal vagotomy due to parasympathetic inhibition.

7752 EFFECTS OF SOMATOSTATIN ON GASTRIC SECRETION AND GASTRIN RELEASE IN MAN. (Eng.) Raptis, S.; Dollinger, H. C.; von Berger, L.; Schlegel, W.; Schroder, K. E.; Pfeiffer, E. F. (Dept. Internal Medicine, Univ. Ulm, Steinhovelstrasse 9, D-79, Ulm, W. Germany). *Digestion* 13(1/2):15-21; 1975.

The effects of somatostatin on gastric secretion and gastrin release in 41 healthy subjects without gastrointestinal symptoms were investigated to determine whether these effects represent a direct action on the gastric secretory cell or they are mediated by pituitary hormones. Synthetic somatostatin (growth hormone release-inhibiting factor, GIF) was used in cyclic (oxidized) and linear (reduced) forms. Cyclic GIF was administered by a 60-min i.v. infusion of 5 μg/min, preceded by an initial dose of 300 μg given i.v. within 30 sec. Linear GIF was given by s.c. injection of 2 mg into each arm. In 9/41 subjects, gastric juice was collected before and during a 150-min infusion of 1 μg/kg/hr synthetic human gastrin (SHG I 1-17). Cyclic GIF significantly inhibited basal gastrin secretion ($p<0.01$) as well as test meal-stimulated gastrin secretion ($p<0.01$), with immediate rebound when the infusion stopped. Similar responses were observed in a hypophysectomized patient, indicating that these effects are independent of suppression of growth hormone. The gastrin levels rose markedly following infusion with SHG I, with a simultaneous increase in gastric acid and pepsin secretion. Fifteen minutes after cyclic GIF infusion, however, there was a significant fall in volume, acid output, and pepsin secretion ($p<0.0125$), although the plasma gastrin concentration remained unchanged. The s.c. injection of linear GIF also caused a significant decrease in stimulated gastric secretion ($p<0.005$) for a period of 165 min. The results show that GIF is a potent inhibitor of gastric secretion and gastrin release.

7753 ANESTHESIA AND STIMULATED GASTRIC SECRETION.

(Eng.) Mason, G. R. (Univ. Maryland Sch. Medicine, 22 S. Greene St., Baltimore, MD 21201). *Chir. Gastroenterol.* 9(4):447-451; 1975.

The effects of various anesthetic agents on the stimulation of gastric acid secretion by insulin, histamine, or gastrin were investigated in mongrel dogs with gastric fistulas or Heidenhain pouches. Insulin alone (10 U, i.v.) caused a reduction of blood sugar to less than 50 mg/100 ml and, after an initial fall, an increase in gastric acid secretion that reached a maximum at 45 min. In anesthetized animals, the secretion of gastric acid fell to near zero within the first 15 min, then reached a peak much smaller than that of controls at 45 min. In three of five animals under halothane anesthesia, four of five under pentothal anesthesia, and all animals under chloralose anesthesia, the decrease in gastric acid secretion was significant. An s.c. injection of histamine phosphate (1 mg) to dogs with Heidenhain pouches resulted in increased gastric acid secretion, which peaked during the second 15-min collection period. Chloralose and pentothal anesthesia slightly, but not significantly, reduced the peak acid secretion, but halothane anesthesia significantly reduced the peak in two of four animals. None of the anesthetic agents reduced the gastric secretory response to gastrin, and both animals tested under chloralose anesthesia had significant increases in acid secretion. It is concluded that the inhibition of acid secretion stimulated by insulin represents an interference with vagal transmission, perhaps by membrane effects. The lack of interference with gastrin stimulation of acid secretion may imply a direct action of this agent on the parietal cell. The inhibition of histamine-stimulated secretion may support the concept that histamine, not acetylcholine, is liberated by vagal stimulation.

7754 NEURAL SYSTEMS RESPONSIBLE FOR THE GASTRIC SECRETION PROVOKED BY 2-DEOXY-D-GLUCOSE CYTOGLUCOPOENIA.

(Eng.) Kadekaro, M.; Timo-Iaria, C.; Valle, L. E. R. (Dept. Physiology and Pharmacology, Inst. Biomedical Sciences, Univ. Sao Paulo, Cx Postal 4365, Sao Paulo, SP, Brazil). *J. Physiol. (Lond.)* 252(3):565-584; 1975.

The central structures responsible for the gastrosecretory effect of cytoglucopenia caused by 2-deoxy-D-glucose (2-DG) were investigated in 105 cats prepared with chronic gastric fistulas and subjected to various experimental procedures. Bilateral electrolytic lesions of the caudalmost two-thirds of the globus pallidus almost suppressed the secretory response (volume, acid concentration, and acid output) to 2-DG (60 mg/kg, i.v.) and caused aphagia and adipsia. The secretory response was blocked ($p<0.01$), along with feeding behavior, after destruction of selected parts of the brainstem. Microinjection of 2-DG (200 μl, 40 mg/ml, over 15 min) in the medial forebrain bundle caused intense gastric secretion, but this procedure was ineffective when the caudalmost globus pallidus was stimulated. Increasing doses of 2-DG (100 or 200 mg/kg), systemically injected, restored the secretory response after intercollicular transection of the brain stem. Secretion of pepsin was only slightly increased, suggesting a differential control of water, acid, and pepsin secretion in response to cytoglucopenia. It is concluded that at least three reflex systems are involved: (1) a reflex consisting of afferent and efferent pathways in the medial forebrain bundle area, (2) a reflex whose afferent side is from the hypothalamus and efferent side is from the globus pallidus, and (3) a reflex whose afferent side probably originates in the liver and efferent side is in the lower brainstem. These three systems are possibly related to control of secretion and feeding behavior.

7755 EFFECT OF BILIARY FISTULA ON CANINE GASTRIC SECRETION.

(Eng.) Kihl, B. O.; Landor, J. H. (Dept. Surgery, CMDNJ-Rutgers Medical Sch., Piscataway, NJ 08854). *J. Surg. Res.* 19(4):245-249; 1975.

The effects of two types of biliary fistula on Heidenhain-pouch secretion were compared in mongrel dogs. For the chronic experiments, a Heidenhain pouch and a Thiry fistula were constructed in each of six dogs, who later underwent ligation and division of the distal common bile duct. Half were fitted with an external biliary fistula (EBF) and half with an ileal biliary fistula (IBF). After 3-4 weeks, the EBF was changed to an IBF and vice versa. For acute experiments, two dogs were prepared with a pouch, a total EBF, gastrostomy, and a Thiry-Vella loop of the ileum. In these dogs, gastric secretion was stimulated by the continuous infusion of pentagastrin peptide (0.75 μg/kg/hr). In the chronic experiments, during the period with the IBF, 24-hr HCl output was higher (19%-105%) in all dogs than it was during the control period ($p=0.0001$). Increases in secretion after IBF (but not EBF) were also significant ($p=0.036-0.0001$). Outputs from the Thiry fistulas were considerably less (33%-42%) with the IBF than with the EBF. In the acute experiments, HCl output during pentagastrin stimulation averaged 2.91 and 1.03 mEq in the two dogs. When bile was placed in the Thiry-Vella loop, the output dropped to 1.03

Eq (p=0.0001) and 0.75 mEq (p=0.0163), resp. hese results show that simple diversion of bile way from the gastrointestinal tract does not result n gastric hypersecretion. They support the contenion that it is the passage of bile through isolated mall intestine, rather than the loss of bile from he gut, that is the critical factor in increasing astric acid production after bile diversion.

756 DISTRIBUTION OF ADENYL CYCLASE SENSITIVE TO HISTAMINE IN RABBIT GASTRIC MUCOSA.

Eng.) Katsumata, Y.; Yagi, K. (Inst. Biochemistry, aculty of Medicine, Univ. Nagoya, Nagoya, Japan). *iochem. Pharmacol.* 25(5):603-604; 1976.

he histological distribution of adenyl cyclase acivity in rabbit gastric mucosa and the effects of ecretion-promoting agents were investigated. Seral tissue sections were incubated in a reaction ixture containing 50 mM Tris-HCl, 5 mM $MgCl_2$, 20 M creatine phosphate, creatine phosphokinase (100 /ml), 1 mM cAMP, and 1 mM ^{32}P-ATP (10-15 cpm/pmol) n the absence and presence of histamine phosphate, etragastrin, or sodium fluoride (NaF). Production f cAMP was linear both with time up to 10 min of ncubation and with protein concentration up to 00 µg/100 µl. Tetragastrin (0.1 mM) did not ncrease the enzyme activity, but histamine (1 mM) nd NaF (10 mM) increased it significantly ($p<0.001$), he latter by 14 times. Adenyl cyclase activity as low in the epithelial cell layer, high in the egion 0.4 mm from the surface (rich in mucous neck ells), low 0.5-0.7 mm from the surface (rich in arietal cells), and high 1.0 mm from the surface rich in chief cells). Histamine increased adenyl yclase activity markedly 0.5-0.7 mm from the surace, and NaF increased the activity in all regions. t is concluded that histamine-sensitive adenyl cycase is related to parietal cells and that histamine s the mediator for gastrin in stimulating gastric cid secretion.

757 OXYGENATION OF FROG GASTRIC MUCOSA IN VITRO.

(Eng.) Kidder, G. W., III; Montgomery, C. . (Univ. Maryland Sch. Dentistry, Baltimore, MD 1201). *Am. J. Physiol.* 229(6):1510-1513; 1975.

It has been shown that 5% CO_2/95% O_2 in the serosal bathing solution with 100% O_2 in the mucosal solution results in CO_2-diffusion limitation of acid secretion in bullfrog gastric mucosa; changing to 10% CO_2/90% O_2 on both surfaces doubles the acid secretory rate. The hypothesis that a significant increase in the rate of oxygen consumption as a result of secretory stimulation would result in the tissue being oxygen-limited was tested. The oxygen tension (pO_2) was raised by increasing the total pressure in a hyperbaric chamber. No change in acid secretory rate or potential difference was observed when the pO_2 was increased from 0.9 to 1.9 atmospheres, indicating that the tissue is not O_2-limited at normal pressure. When the pO_2 was decreased below 0.9 atmospheres, the acid secretory rate was decreased, and both the potential difference and the resistance were increased. The authors conclude that the rate of oxygen consumption did not rise significantly when acid secretion was increased by supplying sufficient CO_2.

7758 MEASUREMENTS OF OXYGEN TENSION FROM THE CANINE GASTRIC MUCOSA UNDER THE INFLUENCE OF VASOACTIVE AND ACID STIMULATING AGENTS AND FOLLOWING VAGOTOMY. IMPLICATIONS ON THE PATHOPHYSIOLOGY OF PEPTIC ULCERATION.

(Eng.) Linder, M. M.; Alken, P.; Muschaweck, R.; Hartel, W. (Chirurgische Klinik des Klinikum Mannheim der Universitat Heidelberg, 6800 Mannheim, Postfach 23, W. Germany). *Z. Exp. Chir.* 9(4):239-245; 1976.

The effect of pharmacologic agents and of vagotomy on the course of mucosal oxygen tension (pO_2) was studied in dogs, and an attempt was made to correlate mucosal pO_2 with gastric pathophysiology. The pO_2 was measured using a multi-wire platinum electrode. The i.v. injection of norepinephrine (2.5 µg/kg) decreased the mean oxygen pressure to 50.8% of the control value (20.4 mm Hg). The minimum value was reached within 38.4 sec, and the pO_2 returned to normal within 106 sec of the injection. A higher dose of norepinephrine (5.0 µg/kg) decreased the pO_2 to 41.3%. The i.v. injection of nafronyl (2.5 mg/kg) increased the mucosal pO_2 to 257% of the control level within 77 sec. The mean arterial blood pressure dropped from 135 to 86 mm Hg within 29 sec and returned to normal within 4 min. The i.v. injection of pentagastrin (0.5-5.0 µg/kg) increased the pO_2 to 174.2% within 116 sec. The mean arterial blood pressure dropped from 136 to 102 mmHg within 39 sec and returned to normal after 5 min. Subdiaphragmatic total vagotomy diminished gastric mucosal pO_2 in six dogs to a mean of 33% of normal within 194 sec. The mean arterial blood pressure remained unchanged. The fall in pO_2 might explain poor results of therapeutic vagotomy in stress ulceration.

7759 THE PEPSINOGENS OF CAT GASTRIC MUCOSA AND THE PEPSINS DERIVED FROM THEM.

(Eng.) Shaw, B.; Wright, C. L. (Medical Sch., The Univ., Newcastle upon Tyne, NE1 7RU, England). *Digestion* 14(2):142-152; 1976.

Fundic mucosal extracts of the cat were examined by chromatography to investigate the pepsinogens and the pepsins derived from them. The peaks of proteolytic activity located by DEAE-cellulose chromatography at pH 5.3 were shown to be heterogeneous on electrophoresis. By electrophoresis of individual homogenous chromatographic fractions, nine separate zones of proteolytic activity were detected. One zone did not migrate from the origin and was possibly a nonpepsinogen gastric protease. Simultaneous electrophoresis of pepsinogens and pepsins indicated that each pepsinogen gave rise to one pepsin. One zymogen gave rise to a pepsin active with the synthetic substrate acetyl-*L*-phenylalanyl-*L*-diiodotyrosine. The proteolytic activity of this enzyme was very low and was most apparent in the pH range 3.1-3.7.

SECRETION AND METABOLISM

Pancreas

7770 A DEMONSTRATION THAT THE RATIOS BETWEEN HUMAN PANCREATIC ENZYMES CAN CHANGE IN 4 DAYS. (Eng.) Allan, B. J.; White, T. T. (Univ. Washington Sch. Medicine, Seattle, WA 98195). *Digestion* 14(3):232-241; 1976.

Pancreatic juice was collected from six patients without known pancreatic disease during the first 6 days after sphincteroplasty. Until the 4th day, patients were on nasogastric suction and were intravenously fed; beginning on the 4th day, they were fed orally. During the first 3 days, flow rates were very low (0.03 ml/min), but on days 4-6 the flow rate was more rapid (0.40 ml/min). Protein concentrations in the two periods were inversely related to flow rates (30-40 mg/ml/8 hr in period I, 2-4 mg/ml/hr in period II). Cellulose acetate electrophoresis of inactive 8-hr collections of pancreatic juice from one patient revealed several differences throughout the observation period. Changes in protein patterns were most marked in the early postoperative period, whereas the patterns on days 4-6 were relatively similar. The band containing amylase was darker on the 1st than the 4th day, while trypsinogen 2 was more prominent on the 4th than on the 1st day. In four of the other five patients, similar patterns were observed for the first 3 postoperative days. Major peaks on the 1st day included amylase, lipase, proelastase, chymotrypsinogen, trypsinogen 1, and unidentified enzymes, and the minor peaks included procarboxypeptidase A, trypsinogen 2, and other unknown bands. The patterns on days 4-6 were more variable.

psinogen 2 was present in much greater amounts
n on the 1st day, and this was confirmed histo-
mically. Histochemical analysis revealed no active
psin or chymotrypsin after electrophoresis. The
erimental variations were not caused by early acti-
ion of the proteases or by the presence of blood
ments. The changes in the trypsinogen 2 and amy-
e content may enable the evaluation of the influ-
e of pancreatic disease on the composition of
creatic secretion.

'1 EXOCRINE PANCREATIC FUNCTION AND CALCIUM
BALANCE. EXPERIMENTAL STUDIES OF THE EF-
T OF PARATHYROID HORMONE, VITAMIN D_3, 25-HYDROXY-
LECALCIFEROL, DIHYDROTACHYSTEROL AND THYROCALCI-
IN. (Ger.) Heidbreder, E.; Sieber, P.; Heidland,
(Med. Univ.-Klinik, Nephrologische Abteilung, D-
0 Wurzburg, Josef-Schneider-Strasse 2, W. Germany).
. *Exp. Med. (Berl.)* 166(2):147-163; 1975.

relation of calcium homeostasis and its deter-
nants to exocrine pancreatic function was genera-
ed in experiments on perfused cat pancreas. Ele-
ion of calcium ions in the perfusate elicited in-
eased protein and enzyme release; a continuous cal-
m supply failed to raise pancreatic calcium sec-
ion, except transiently. Extracellular calcium
a direct, temporary acinar effect. Vitamin D_3,
hydroxycholecalciferol (HCF), and dihydrotachy-
erol had no effect on pancreatic secretion dynamics.
flow rate remained constant, and calcium excre-
n was unchanged. Acetylcholine (ACTH) or chole-
tokinin (CK)-pancreozymin (PM) stimulation of pro-
n or enzyme was increased after HCF challenge.
hough vitamin D_3 altered intestinal calcium trans-
t, it had no gastric or pancreatotropic effect.
g-term parathyroid hormone affected neither the
w rate nor electrolyte liberation, but inhibited
tein excretion after CK-PM or ACTH stimulation;
protein suppression was potentiated by simulta-
usly increasing the extracellular calcium concen-
tion. The addition of vitamin D_3 or HCF neutral-
ed the protein-damping effect of parathyroid hor-
e, as the pancreas is not a target tissue of it.
rocalcitonin also depressed CK-PM- or ACTH-stimu-
ed protein, if the extracellular calcium remained
stant; it had no effect on the flow rate or cal-
m secretion. Whether the reduced protein and
zyme pattern is the initial pathogenetic phase of
creatic dysfunction and can serve as a model of
ercalcemic pancreatitis remains controversial.

'2 REGULATION OF PANCREATIC AND GALLBLADDER
FUNCTIONS BY INTRALUMINAL FATTY ACIDS AND
E ACIDS IN MAN. (Eng.) Malagelada, J.-R.; Di-
gno, E. P.; Summerskill, W. H. J.; Go, V. L. W.
astroenterology Unit, Mayo Clinic and Mayo Found-
ion, Rochester, MN 55901). *J. Clin. Invest.* 58
):493-499; 1976.

effects of intraduodenal glycerol, fatty acids
) chain length and FA loads, and bile acid (BA)
ncentrations on pancreatic and gallbladder func-
n were investigated in 31 healthy volunteers by
perfusion method. The FA absorption rates in the
duodenum and proximal jejunum were measured simultaneously. All individuals received two different test solutions during separate 100-min perfusions. The test solutions all contained the bile acid sodium taurocholate (10 mM) plus oleic (C18), lauric (C12), or octanoic acid (C8). Pancreatic enzyme outputs evoked by all three FA at 20 mM were above basal values ($p<0.05$). C18 was more potent than C12 and both were more potent than C8 ($p<0.01$). Bilirubin outputs were greater than control values with C18 and C12 ($p<0.01$) but not with C8. (The responses increased with increasing chain length). C18 at 20 or 30 mM (but not 10 mM) caused a striking elevation in bilirubin output ($p<0.01$). Increasing the BA concentration from 1 to 10 mM decreased the pancreatic enzyme outputs otherwise stimulated by C18 ($p<0.02$) and decreased the enzyme response to C8 ($p<0.05$). At 20 mM, outputs in response to C18 increased to values obtained at 1 mM BA. High bilirubin outputs were obtained with C18 ($p<0.01$) or C8 ($p<0.05$) perfused with 1 mM BA. Outputs declined to basal levels with 10 mM BA but increased again with 20 mM BA. BA concentration of 1-10 mM accelerated FA absorption but decreased the magnitude of pancreatic and gallbladder responses to FA. BA concentrations of 10-20 mM had the opposite effect. A significant, inverse correlation was found between FA absorption and pancreatic and gallbladder responses to FA, suggesting a relation between the length of the intestine exposed to FA and the amount of cholecystokinin, which stimulates pancreatic secretion and gallbladder contraction, released.

7773 EXOCRINE PANCREATIC FUNCTION IN MAN AFTER TREATMENT WITH OXYTETRACYCLINE AND CHLORAMPHENICOL. (Eng.) Fleischer, K. (Medizinische Klinik des Universitat Wurzburg, Luitpoldkrankenhaus, D-87 Wurzburg, W. Germany). *Digestion* 14(2): 108-116; 1976.

Pancreatic exocrine function was evaluated by a secretin-cholecystokinin test before and after treatment with oxytetracycline (OTC, 250 or 500 mg, twice daily, x 3 or 6 days) or chloramphenicol (CAP, 1 g, three times daily, x 3 or 6 days). OTC was administered to 14 men, either healthy or with chronic pancreatitis, and CAP was given to 7 similar men.
The control group consisted of 22 healthy adult men. At the lower dose, OTC did not affect the volume of secretion, maximum bicarbonate concentration, or sodium secretion. At 500 mg, OTC resulted in a fall in volume in four of six subjects, while the maximum bicarbonate output increased in three and decreased in three others. Sodium secretion followed the volume of secretion, but calcium secretion showed a nearly uniform decline after both doses. Trypsin and chymotrypsin outputs after 250 mg OTC were essentially unchanged, while after 500 mg, there was a slight decrease in chymotrypsin. Amylase activity was distinctly reduced in all but two subjects after either dose, and lipase was reduced in the majority of cases. After CAP, the volume, sodium, and maximum bicarbonate concentration were unaffected. Calcium levels declined in five subjects, were unchanged in one, and increased in one. Outputs of trypsin, chymotrypsin,

and lipase did not show any uniform pattern, but amylase activity decreased distinctly in four subjects, was unchanged in two, and increased in one. The patterns after 6 days of either drug were not different from those after 3 days. There were no significant changes in the individual parameters when patients with pre-existing pancreatic insufficiency were compared with normal subjects. Following 250 mg of OTC, serum levels at 6 and 12 hr after injection averaged 4 and 2.27 μg/ml, resp. Corresponding values after 500 mg OTC were 6.4 and 4.65 μg/ml. At 8 hr after administration of CAP, serum levels averaged 13.4 μg/ml. The effects on enzyme production are considered to reflect the onset of pancreatic dysfunction due to antibiotic administration, resulting in inhibition of protein synthesis.

7774 CONTINUOUS SECRETIN INFUSION WITH PANCREOZYMIN PRETREATMENT AS A PANCREATIC FUNCTION TEST. (Eng.) Takebe, T.; Koizumi, H.; Yamagata, S. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 118(Suppl.):173-181; 1976.

The results of a pancreatic function test with a submaximal dose of secretin given by continuous infusion after the injection of submaximal doses of cholecystokinin-pancreozymin (CCK-PZ) are described. Twenty healthy male students were given 1 U/kg of CCK-PZ by constant infusion over a 5-min period, followed by a continuous i.v. infusion of secretin (1.2 Crick-Harper-Raper U/kg/hr) over a 90-min period. Continuous suction aspiration of duodenal contents was performed during nine consecutive 10-min collection periods. The highest volume of output was in the first fraction, after which the volume leveled off at approximately 30 ml per fraction, with a slight increase in the ninth fraction. The icterus index was highest in the initial fraction and then rapidly decreased in the next two fractions. The icterus index was essentially constant in the fourth through sixth fractions and showed a slight increase in the seventh to ninth fractions. This suggested that the first three fractions were biliary, and the subsequent fractions were pancreatic. The bicarbonate concentration increased gradually and became constant at 110-115 mEq/l after the fifth fraction. The bicarbonate output was less in the second fraction than in the first, then gradually increased and became constant in the fifth through the ninth fractions. The highest amylase concentration and output were found in the initial fraction, after which both parameters were essentially constant until the eighth fraction, in which both were again slightly increased. The coefficients of variation in the volume output and the bicarbonate concentration were calculated to be about 15 and 5%, resp. These variations were considerably smaller than those encountered in the standard secretin test, because of the elimination of bile contamination. It is suggested that if a pure and well standardized secretin preparation is available, this test may become a useful tool for the early diagnosis of pancreatic disease.

SECRETION AND METABOLISM

Hepatobiliary Tract

7784 COVALENT BINDING: USEFUL INDEX OF THE FORMATION OF CHEMICALLY REACTIVE DRUG METABOLITES. (Eng.) Mitchell, J. R. (Lab. Chemical Pharmacology, Natl. Heart and Lung Inst., NIH, Bethesda, MD 20014). *Biochem. Soc. Trans.* 3(5):622-626; 1975.

The role of covalent binding in drug-protein interactions is reviewed, and its use as an index of the formation of chemically reactive drug metabolites is proposed. These metabolites have been implicated as mediators of the hepatic necrosis produced in animals by several common hepatotoxic drugs, such as acetaminophen (4'-hydroxyacetanilide; paracetamol). At therapeutic doses, this analgesic is rather safe. But at large doses, it can produce fatal centrilobular liver necrosis in man and experimental animals. In mice, little covalent binding occurred until the dose reached the toxic value (>300 mg/kg). The glutathione concentration in the liver decreased as the dose of the drug was increased, suggesting that glutathione inactivated a chemically reactive metabolite and, thereby, prevented covalent binding and necrosis. Since acetaminophen is chemically stable, the finding of a covalent linkage with macromolecules of the liver demonstrates that it was converted in the body into reactive alkylating, arylating, or acylating agents. Pretreatment of mice with inducers of metabolism, such as phenobarbital, or with inhibitors of metabolism, such as piperonyl butoxide and $CoCl_2$, similarly altered the drug metabolism rate, the severity of necrosis, and the extent of hepatic binding of radiolabeled metabolites.

7785 TWO-COMPARTMENT MODEL FOR HEPATIC DYE EXCRETION DURING INTRAVENOUS INFUSION. (Ger.) Towe, J.; Brugmann, E. (Bereiches Medizin, Universitat Rostock, 25 Rostock, Leninallee 70, E. Germany). *Wiss. Z. Univ. Rostock* [*Math.-Naturwiss. Reihe*] 23(4/5):359-362; 1974.

The principle of constant infusion is interpreted on the basis of Richards' linear two-compartment model and applied to dye excretion in the liver. The blood, the biliary-intestinal system, and the liver are construed as homogeneous pools, whose sizes depend only on the amount of dye in each. The temporal change of dye in a pool simply depends on the difference between inflow and outflow per unit of time; and the flow from a pool is proportional to available dye. Conventional differential equations describing the time change in the amount of dye in the blood and liver can be used to find the various transport values between compartments, which describes the status of the liver. A saturation of dye concentration is rapidly reached in normal patients. In liver cirrhosis, the saturation is never reached; in the example provided, saturation was not reached by a constant 1-hr infusion. The dye concentration in the blood compartment is maximal in this case, since dye transport from blood to the liver is delayed in cirrhosis patients.

7786 BILIARY EXCRETION OF DYE IN DOGS INFUSED WITH BSP OR ITS GLUTATHIONE CONJUGATE. (Eng.) Barnhart, J. L.; Combes, B. (Univ. Texas Southwestern Medical Sch., Dallas, TX 75235). *Am. J. Physiol.* 231(2):399-407; 1976.

To determine whether conjugation of BSP facilitates dye excretion in the dog as it does in other species, the maximal rates of biliary excretion (Tm) of dye in dogs infused with either BSP or its glutathione conjugate (BSP-GSH) were compared. The mean Tm when BSP-GSH (14.4 μmol/ml, 0.9 ml/min) was infused was much higher (0.325 μmol/min/kg) than when BSP (8.0 μmol/ml) was infused (0.161 μmol/min/kg). The higher values for Tm during BSP-GSH infusion were accounted for entirely by a higher concentration of dye in bile (mean 29.0 μmol/ml versus 15.8 μmol/ml). When BSP and BSP-GSH were infused together, unconjugated BSP was soon detected in the bile. The rate of excretion of conjugated BSP into bile fell simultaneously and to a greater extent than the rate of appearance of unconjugated dye in the bile. As a result, total dye excretion fell. These results suggest that BSP and its conjugated metabolites compete for a common transport carrier and that BSP disproportionately depresses the biliary excretion of conjugated dye compounds; the latter observation accounts for the depressed dye Tm found during BSP infusion. Dye Tm was established during the simultaneous infusion of sodium taurocholate (0.77-2.71 μmol/min/kg) and either BSP-GSH or BSP. During the choleresis induced by increased bile salt excretion, dye excretion invariably rose. The slopes of the relation of dye excretion and bile salt excretion were comparable when either BSP or BSP-GSH were infused, although the absolute values for dye excretion at any value of bile salt excretion were higher during BSP-GSH infusion. Since increments of canalicular bile flow induced by the administration of theophylline (21 mg/kg, i.v.) or glucagon (5 μg/min) did not enhance dye excretion into bile, the enhancement of dye Tm during BSP-GSH infusion appears to be related to taurocholate excretion *per se*, rather than to the enhanced canalicular bile flow that accompanies its excretion. Furthermore, data on hepatic dye content and composition indicate that enhanced dye excretion with taurocholate is not accounted for by an alteration in dye composition in the liver. Rather, the two forms of dye are transported more readily into bile.

7787 THE ROLE OF GLUTATHIONE IN CHLOROFORM-INDUCED HEPATOTOXICITY.

(Eng.) Docks, E. L.; Krishna, G. (Lab. Clinical Pharmacology, National Heart and Lung Inst., NIH, Bethesda, MD 20014). *Exp. Mol. Pathol.* 24(1):13-22; 1976.

The role of glutathione (GSH) in chloroform-induced liver cell necrosis was investigated in male Sprague-Dawley rats. Rats were pretreated with phenobarbital (80 mg/kg, i.p.), 3-methylcholanthrene (20 mg/kg, i.p.), acetone (2.5 ml/kg, p.o.), or isopropanol (2.5 ml/kg, p.o.) prior to injection of ($CHCl_3$) chloroform. In phenobarbital-pretreated rats, $CHCl_3$ (0.2 ml/kg, i.p.) decreased liver GSH (to 6.02 μmol/g from a control value of 9.04; $p<0.001$) and caused massive liver necrosis. Only those doses of $CHCl_3$ that decreased GSH in the liver caused centrilobular liver necrosis. Other halogenated alkanes studied, including CCl_4 and CCl_3Br, did not deplete GSH in phenobarbital-pretreated rats. In rats pretreated with 3-methylcholanthrene, isopropanol, or acetone, which also increase drug metabolism, $CHCl_3$ (0.5 to 1.0 ml/kg) did not markedly decrease GSH in the liver. The GSH depletion was not due to oxidation of GSH or to inhibition of GSH reductase, because $CHCl_3$ did not increase the amount of oxidized GSH in liver, whole blood, or kidney. Since only liver GSH was depleted, it appeared that the depletion was related to $CHCl_3$ metabolism. Since CCl_4 and CCl_3Br are postulated to form the trichloromethyl free radical (CCl_3) and since these compounds do not deplete liver GSH in phenobarbital-pretreated rats, GSH depletion by $CHCl_3$ may be due to formation of chemically reactive metabolites other than this radical.

7788 HEPATIC UPTAKE OF ASIALOGLYCOPROTEINS IN VIVO: QUANTIFICATION USING A DUAL-ISOTOPE TECHNIQUE.

(Eng.) Regoeczi, E. (Dept. Pathology, McMaster Univ., 1200 Main St. West, Hamilton, Ontario, Canada, L8S 4J9). *J. Nucl. Biol. Med.* 19(3):149-154; 1975.

A method for the short-term measurement of the hepatic clearance of asialoglycoproteins in rats was developed. The rate of clearance is determined from the quantity of radioactive test protein that has accumulated in the liver during an interval that is shorter than the time required for the complete elimination of the dose from the plasma. This is made possible by the introduction of a separate marker for trapped hepatic plasma. Human serum albumin, human transferrin, and human and rat α_1-acid glycoproteins (AGP) were examined for their potential value as trapped plasma markers. The human serum albumin was found to be the best plasma marker because it was free of denatured material. Human AGP consistently gave higher estimates for trapped plasma volume in the liver than human serum albumin, because it was taken up to some extent by the rat liver. If rats were preinjected with an excess (2.3-3 mg/100 g) of unlabeled human or chicken AGP, the volume indicated by human AGP (labeled with ^{125}I or ^{131}I) appeared to be correct. Preloading of rats with rat AGP had no similar correcting effect on human I-AGP as a marker. Using I-labeled human serum albumin as a marker, the radioactivity representing trapped plasma in the liver corresponded, on the average, to 7.7% of the dose, and it was never less than 5%. Lower values can be taken as a sign for mixed intra- and paravenous injection. The need for a method for the short-term measurement of the hepatic clearance of asialoglycoproteins is twofold. In view of its rapid elimination, asialo-orosomucoid cannot be accommodated in a clearance system that runs longer; and previous experiments have indicated that hydrolysis of the endocytized asialoglycoprotein gives rise to losses of radioactivity from the liver as early as 20-30 min after injection.

7789 INVESTIGATIONS ON THE EXTENT OF LIVER LESIONS IN RATS BY EXPERIMENTAL INHALATION POISONING WITH CARBON DISULFIDE. II. ANALYSIS OF BIOCHEMICAL CHANGES IN LIVER HOMOGENATE AND ITS FRACTIONS.

(Ger.) Gregorczyk, J.; Wieckowski, B.; Wesolowska, T. (Instytut Chorob Wewnetrznych PAM. Al. Postancow 72, 70-111 Szczecin, Poland). *Int. Arch. Arbeitsmed.* (34):151-166; 1975.

The biochemical and morphological changes in rat hepatocytes resulting from CS_2 challenge were investigated. Adult male Wistar rats were exposed to CS_2, 1.33 mg/l of air, in a closed chamber for 12 weeks, 4 days/week, 5 hr/day (group A); 26 weeks, 4 days/week, 5 hr/day (group B); or 10 weeks, 4 days/week, 10 hr/day (group C). Liver homogenization and subcellular fraction preparation followed sacrifice at 72 hr after the final CS_2 exposure. Malic dehydrogenase (MDH), LDH, asparagine aminotransferase, alanine aminotransferase, and acid phosphatase in the total homogenate and in mitochondrial, light mitochondrial, heavy microsome, and supernatant fractions showed no significant difference between control and experimental groups (each group with 26 animals). In group B, glucose-6-phosphatase in total homogenate was depressed to 15.4 U/mg protein compared to 24.5 for controls ($p<0.02$). The percent of total MDH isoenzyme 2 activity in the supernate was depressed to 43.6 from a control level of 49.8 ($p<0.05$) in group A, and to 44.3 from 50.6 ($p=0.05$) in group B. Mitochondrial MDH isoenzyme 3 was decreased (percent of total activity) from 34.8 for the controls to 29.3 ($p<0.01$) in group B. Supernate MDH3 was increased (in percent) from 47.4 (controls) to 52.9 in group A and from 46.8 (controls) to 52.2 in group B ($p<0.05$). In the LDH spectrum, only the LDH5 profile decreased in total homogenate, in percent of total activity, from 89.2 to 83.9 ($p<0.05$

in group A and from 90.4 to 87.5 ($p<0.05$) in group B. Protein from homogenate and supernate showed no difference in total amount or in electrophoretic separation, nor was there any group difference in alpha-amino acids or 16 free amino acids. The biochemical modifications are attributed to host adaptation and not to CS_2 toxicity.

7790 THE ISOLATED HEPATOCYTE AS THE TARGET CELL OF IMMUNOLOGICAL REACTIONS. (Ger.) Hopf, U. (II Med. Univ.-Klinik, 65 Mainz, Langenbeckstrasse 1, W. Germany). *Z. Gastroenterol.* 13(Suppl.):289-291; 1975.

A brief review of the isolated hepatocyte in cytotoxic immune reactions is presented. The antigenic structure of the hepatocyte membrane, cell vitality indices, modalities of liver cell cultures, *in vitro* cytotoxicity, and membrane-bound immunoglobulins were topically discussed. There is no presently satisfactory test system for demonstrating cytotoxic immune reactions in the isolated hepatocyte. Unpublished studies of hepatocytes harvested from punch biopsies of metabolic or inflammatory liver disease patients are cited. Incubated with FITC-labeled human immunoglobulin (Ig) G rabbit antisera, a membrane-bound IgG could be detected in 9/34 patients with acute viral hepatitis B and 17/54 cases with chronic active hepatitis. Patients with acute viral hepatitis A, chronic persisting hepatitis, or metabolic disease were negative. The predominantly hepatitis B surface antigen (HBsAg)-positive chronic active hepatitis cases receiving immunosuppressive therapy had IgG on the hepatocytes, but serum antibodies against HBsAg could not be demonstrated, and autoimmune phenomena were rare.

7791 SITE OF BILE ACID ABSORPTION IN THE RAT. (Eng.) Sklan, D.; Budowski, P.; Hurwitz, S. (Faculty of Agriculture, Hebrew Univ. Jerusalem, Rehovot, Israel). *Lipids* 11(6):467-471; 1976.

The site and extent of bile acid absorption were measured *in vivo* in the isolated small intestine of male CR rats using $^{91}YCl_3$ (25-50 μCi/kg in the diet) as a nonabsorbed reference substance. Independently, the uptake and transfer of bile acids from ligated intestinal segments were measured *in situ*. Mucosal and serosal transport of 0.015 μCi tauro(^{14}C-carbonyl)cholic acid in 0.5 ml test solution was measured in intestinal loops. The secretion of bile acids into the duodenum was 9 g/kg/24 hr. Around 50% of the bile acids found in the duodenum were absorbed in the proximal half of the small intestine, but the absorption of bile acids by the entire small intestine amounted to 90%. *In situ*, the percentage of mucosal uptake was greater in the ileal loop, but the absolute mucosal uptake of bile acids was greater in the jejunal loop. Serosal transfer was lower in the jejunal loop than in the ileum, whether expressed as absolute or percentage transfer. Serosal transport is the limiting stage of bile acid absorption in the jejunum, but not in the ileum. The percentage mucosal uptake (28%) and the percentage serosal transfer (11%) in the jejunum remained constant upon incubation with either 4 or 8 mg/ml bile acids. Increasing bile acid concentrations did not affect the percentage disappearance of dose from the jejunum, but they reduced the percentage mucosal uptake in the ileum. It is concluded that in the rats the proximal small intestine is as important in the absorption of bile acids as the distal small intestine.

7792 BILE ACID METABOLISM IN MAMMALS. VIII. BILIARY SECRETION OF CHOLYLARGININE BY THE ISOLATED PERFUSED RAT LIVER. (Eng.) Yousef, I. M.; Fisher, M. M. (Dept. Medicine, Univ. Toronto, Toronto, Ontario M5S 1A8, Canada). *Can. J. Physiol. Pharmacol.* 53(5):880-887; 1975.

The characterization and identification of cholylarginine formed during the metabolism of cholic acid in the isolated perfused Wistar rat liver system were investigated. Cholic acid (30 μmol) was added to the medium, and the perfusion was continued for 3 hr. Thin-layer chromatography of the secreted bile showed four bile acid conjugates with R_f values of 0.24 (cholyltaurine), 0.40 (unknown compound I), 0.49 (cholylglycine), and 0.85 (unknown compound II, much more polar than free cholic acid). Gas-liquid chromatography showed that compound II had a molecular weight greater than that of cholyltaurine. The retention times relative to cholylglycine were compound I, 1.15; cholyltaurine, 1.54; and compound II, 1.90. It comprised 15%-27% of the biliary bile acids in these experiments. Amino acid analysis of the hydrolyzed conjugate demonstrated the presence of arginine. Perfusion studies with radioactive arginine and mass spectrometry of the acetyl derivative of the methyl ester of compound II proved that it was cholylarginine.

7793 BILE ACIDS: XLVII. 12α-HYDROXYLATION OF PRECURSORS OF ALLO BILE ACIDS BY RABBIT LIVER MICROSOMES. (Eng.) Ali, S. S.; Elliott, W. H. (Dept. Biochemistry, Univ. Karachi, Karachi, Pakistan). *Biochim. Biophys. Acta* 409(2):249-257; 1975.

The effects of several parameters on the rate of 12α-hydroxylation of 3β-^{3}H- or 24-^{14}C-allochenodeoxycholic acid and $5\alpha,6\alpha$-$^{3}H_2$-5α-cholestane-3α,7α-diol by rabbit liver microsomal preparations fortified with NADPH were investigated. Microsomal preparations fortified with 0.1 mM NADPH effectively promoted hydroxylation of the two acids and the diol to their respective 12α-hydroxyl derivatives in yields of about 25% or 65% in 60 min. Minor amounts of other products were formed with the diol. The requirements for activity of rabbit liver microsomal 12α-hydroxylase resembled those of rat liver microsomes; i.e., 0.1 mM NADPH is a necessary cofactor. 12α-Hydroxylase activity was significantly reduced after 2-7 weeks storage at -20 C. Metal chelating agents such as o-phenanthroline and EDTA did not inhibit 12α-hydroxylation to a significant extent. Striking inhibition (92%-94%) occurred only with 1 mM p-chloromercuribenzoate. Addition of 10 mM glutathione to the incubation mixture enhanced the reaction up to 75% for allochenodeoxycholic acid and 16% for the diol. There was no difference in the quantity of product produced from the ^3H- or the ^{14}C-labeled acid. No clear sex or age difference was found in the enzyme activity.

7794 PURIFICATION AND PROPERTIES OF ALKALINE PHOSPHATASE FROM HUMAN BILE. (Eng.) Sugiura, M.; Hirano, K.; Iino, S.; Suzuki, H.; Oda, T. (Dept. Pharmacy, Tokyo Coll. Pharmacy, Ueno-Sakuragi, 1-Chome, Taito-ku, Tokyo, 110, Japan). *Chem. Pharm. Bull. (Tokyo)* 23(9):2019-2024; 1975.

Alkaline phosphatase (AP) from human bile was purified by butanol treatment, protamine sulfate treatment, diethylaminoethyl (DEAE)-cellulose, carboxymethyl cellulose, DEAE-Sephadex A-50 chromatography and Sephadex G-200 gel filtration. The enzyme was purified 15,000-fold, and its homogeneity was confirmed by disk electrophoresis. The recovery of AP was poor, mainly because of the great drop of activity during gel filtration. The addition of 10^{-5} M $ZnCl_2$ and $MgCl_2$ to the buffer solution prevented this drop to a certain extent. The molecular weight of AP was 180,000 daltons. The purified enzyme was similar to human placental and intestinal AP with respect to the influence of various compounds [marked inhibition by 10^{-3} and 10^{-4} M EDTA (to 2% and 37%, resp.) and N-bromosuccinimide (to 1% and 7%)], optimum pH (10.5), pH stability (4-11), and isoelectric point (4.75). However, Mg^{2+} and Zn^{2+} ions activated the biliary AP to a greater extent than the human placental and intestinal forms. The thermal stability of biliary AP was similar to that of intestinal AP, but different from the placental enzyme. Because the biliary AP was inhibited to 69% and 74% activity by homoarginine (10^{-3}-10^{-4} M), a strong inhibitor of liver AP, it is suggested that the biliary form originated from the liver. It was not inhibited by L-phenylalanine, which does inhibit placental and intestinal AP.

7795 RELEASE OF VITAMIN B_{12}-BINDING PROTEIN FROM ISOLATED RAT LIVER PERFUSED WITH A SYNTHETIC MEDIUM. (Eng.) Novakova, V.; Gullberg, R. (King Gustaf Fifth Res. Inst., Stockholm, Sweden). *Acta Physiol. Scand.* 96(4):500-505; 1976.

Studies were carried out to determine whether the unsaturated vitamin B_{12}-binding capacity (UBBC) of the small molecular sized vitamin B_{12}-binding protein (SBP) released by the isolated rat liver reflects the condition of the liver. Changes in the UBBC of SBP were compared with the release of albumin into a perfusion medium and with the fluid pressure in the portal vein under various conditions. When Sprague-Dawley rat livers were perfused with medium containing a gas carrier (FC-80) at a high flow rate (52 ml/min), the functional state of the liver during the first 3 hr of perfusion was good, as indicated by a high level of albumin release (2.1 mg/hr/100 g) and a low stable portal pressure. The rate of increase in UBBC of SBP release during this time was 20,000-50,000 pg B_{12}/hr/100 g of donor body weight. After the third hour, the rates of albumin and UBBC of SBP release decreased and portal pressure increased, reflecting the formation of fibrin which blocked the vascular system and produced hypoxia. In another series, the liver was also perfused with medium containing gas carrier, but at a slower rate (24 ml/min). The UBBC of SBP at 3 hr was lower (8,000-15,000 pg/hr/100 g) than in the first experiment. The albumin level increased continuously during this experiment, but at a lower level (0.48 mg/hr/100 g). When liver damage was induced after 3 hr by the addition of noradrenalin (100 μg/80 ml medium/hr), the deterioration of liver function was reflected by an increase in portal pressure and a decrease in UBBC of SBP, but not by a decrease in albumin release. In a series of experiments in which no gas carrier was used and the perfusion was carried out at 24 ml/min, hypoxia was reflected by decreases in albumin release and UBBC of SBP (600-9,000 pg/hr/100 g during the first 3 hr) but not by an increase in portal pressure. These experiments demonstrate that the fluid pressure in the portal vein is an accurate indicator of the circulatory state of the perfused liver, but is not always an indicator of the condition of the liver. Albumin release is a good indicator of the functional state, but seems to respond slowly to liver damag However, the amount of UBBC of SBP release sensitively reflects both functional capacity to produce proteins and the presence of liver damage.

7796 KINETICS OF HEPATIC UPTAKE OF UNCONJUGATE BILIRUBIN. (Eng.) Paumgartner, G.; Reichen, J. (Dept. Clinical Pharmacology, Univ. Berne, Murtenstrasse 35, CH-3010 Berne, Switzerland). *Cli Sci. Mol. Med.* 51(2):169-176; 1976.

Hepatic bilirubin uptake was studied in the perfuse Sprague-Dawley rat liver by a multiple-indicator dilution technique, to study the kinetics of bilirubin uptake and to determine whether bilirubin and bile acids enter the hepatocyte via a common or separate pathway. The kinetics of hepatic bilirubin uptake could be described by the Michaelis-Menten equation. The maximal uptake velocity (V_{max}) and the apparent half-saturation constant (K_m) were 4.4 ± 0.5 nmol/sec/g of liver and 58 ± 16 nmol/g of liver, resp., indicating that the hepatic uptake sy tem for bilirubin under normal conditions is operat far below saturation. Sodium taurocholate did not compete with bilirubin for hepatic uptake. These findings are consistent with the concept that carri mediated transport is responsible for hepatocellula uptake of bilirubin and that bilirubin and bile acids enter the hepatocyte via separate pathways.

7797 ON THE AUTOXIDATION OF BILIRUBIN. (Eng.) Lightner, D. A.; Cu, A.; McDonagh, A. F.; Palma, L. A. (Dept. Chemistry, Univ. Nevada, Reno, NV 89507). *Biochem. Biophys. Res. Commun.* 69(3): 648-657; 1976.

The instability of various oxygenated aqueous solutions of bilirubin (BR) in the dark was investigate The disappearance of BR was monitored spectrophotometerically by recording the visible spectrum of each solution at 1-hr intervals and after the decrease of the absorbance maximum of BR near 440 nm.

Solutions were either purged with Ar and then kept stoppered in the dark or subjected to O_2 or N_2 bubbling. Autoxidation occurred in aqueous solutions over a pH range 7.4-13.2 in the presence of even traces of oxygen. At pH 7.4-8.9, bilirubin precipitated from 2.5×10^{-5} M solutions and adsorbed to the walls of the glass container. In ammonical methanol, chloroform, and dimethyl sulfoxide, aggregation phenomena did not occur and autoxidation was very slow. No unusual buffer effects were observed, but there was a trend toward a greater degree of autoxidation with increasing pH. This trend may be more apparent than real, since at the lower pH values the amount of BR truly in solution and available for autoxidation was progressively reduced by aggregation. These studies showed that the instability of aqueous solutions of BR in the dark is due to autoxidation, aggregation, and surface adsorption.

7798 EARLY INHIBITION OF HEPATIC BILIRUBIN CONJUGATION AFTER PARACETAMOL (ACETAMINOPHEN) ADMINISTRATION IN THE RAT. (Eng.) David, M.; Ideo, G.; Harrison, N. G.; Williams, R. (Liver Unit, King's Coll. Hosp. and Medical Sch., Denmark Hill, London SE5 8RX, England). *Digestion* 13(1/2):42-48; 1975.

The early inhibition of hepatic bilirubin conjugation after administration of paracetamol (acetaminophen; 13.3 mmol/kg body weight) was investigated in male Wistar rats. The drug was administered in an aqueous suspension by stomach tube. In rats killed 48 hr later, mild centrilobular hepatic necrosis and elevated plasma aspartate aminotransferase levels were found. The histology and enzyme levels were normal 2 hr after dosing. Control and paracetamol-treated animals given i.v. bilirubin loads (35 μmol/kg) and killed 5 min after injection had similar plasma bilirubin levels (245 and 248.9 μmol/liter, resp.); 98%-100% was unconjugated. The total hepatic bilirubin content was also similar (12.8 and 13.6 nmol/g liver, resp.). However, only 28% was unconjugated in the controls, but in the treated animals this form accounted for 56% of the total ($p<0.001$). At 30 min, plasma bilirubin levels were higher in the treated animals, a result of an increase in the unconjugated fraction (126.1, versus 71.6 μmol/liter in controls). Hepatic total bilirubin levels were also higher in treated animals than in controls (11.0 and 7.0 nmol/g liver, resp., $p<0.001$), due to an increase in both forms ($p<0.005$). Hepatic activities of bilirubin uridine diphosphate-glucuronyltransferase were similar in the two groups. Bile flows were higher ($p<0.05$) in the treated rats, but bilirubin concentration ($p<0.001$) and its excretion ($p<0.02$) were lower than in the controls. Hepatic glucuronide conjugation is impaired early after paracetamol overdose; the impairment precedes the accumulation and binding of the hepatotoxic metabolite of the drug within the liver cells.

7799 BIOCHEMICAL CHANGES AFTER HEPATIC INJURY FROM TOXIC DOSES OF ACETAMINOPHEN OR FUROSEMIDE. (Eng.) Thorgeirsson, S. S.; Sasame, H. A.; Mitchell, J. R.; Jollow, D. J.; Potter, W. Z. (Lab. Chemical Pharmacology, Natl. Heart and Lung Inst., NIH, Bethesda, MD 20014). *Pharmacology* 14(3):205-217; 1976.

The effects of hepatotoxic doses (400 mg/kg, i.p.) of acetaminophen (AAP) and furosemide (FE) on the function and composition of hepatic endoplasmic reticulum were compared 3-24 hr after administration to GP mice and male Syrian hamsters. Liver sections, obtained 6, 12, or 24 hr after drug administration, demonstrated a striking centrilobular (with AAP) or midzonal-centrilobular necrosis (with FE), involving from 10%-40% of the parenchymal hepatocytes. Twelve hours after administration of FE, the triglycerides were significantly decreased (5.44 mg/g liver versus 13.32 mg for controls; $p<0.05$), but treatment with 2,000 mg/kg carbon tetrachloride markedly increased these compounds (24.67 mg; $p<0.05$). AAP caused a significant decrease in microsomal protein concentration as early as 3 hr after administration (9.1 mg/g liver versus 14.5 mg for controls; $p<0.05$); FE did not produce any decreases until 24 hr (8.6 mg; $p<0.05$). Cytochrome P-450 concentrations declined to 48% and 32% of control values at 12 and 24 hr, resp., after AAP and to 57% and 36% at 12 and 24 hr, resp., after FE. Cytochrome b_5 was also decreased, but not as much. Loss of microsomal heme was proportional to the observed decreases in the cytochrome. NADPH cytochrome c reductase was impaired only at 24 hr after administration of either drug. Microsomal ethylmorphine N-demethylase and aniline hydroxylase activities were decreased by both drugs, but glucose-6-phosphatase and uridine diphosphate-glucuronyltransferase were not affected significantly. Incorporation of ^{3}H-L-leucine into liver proteins was decreased 50% by AAP or FE. Administration of AAP and FE to adult mice produced structural changes in the hepatic endoplasmic reticulum and alterations in some membrane-related functions within 24 hr. However, the distorted function is not only due to destruction of the smooth endoplasmic reticulum, since some membrane-associated functions remained.

7800 EVIDENCE FOR THE POSSIBLE FORMATION OF A TOXIC TYROSINE METABOLITE BY THE LIVER MICROSOMAL DRUG METABOLIZING SYSTEM. (Eng.) David, J. C. (U.E.R. de Biochimie, Faculte des Sciences, 2, place Jussieu, F-75005 Paris, France). *Naunyn Schmiedebergs Arch. Pharmacol.* 292(1):79-86; 1976.

The possibility that the liver microsomal drug-metabolizing system might metabolize tyrosine to a toxic compound was explored. The effects of several inducers and inhibitors of this system were measured in decarboxylase-inhibited [50 mg/kg N_1-(DL-seryl)-N_2-(2,3,4-dihydroxybenzylhydrazine, i.p., twice daily)] male MF_1 mice given 0.5-3.5 g/kg tyrosine, p.o., twice daily. Pretreatment of mice with 50 mg/kg SKF 525A (2-diethylaminoethyl-2,2-diphenylvalerate, HCl), i.p., or 60 mg/kg cobaltous chloride, i.p., increased the LD_{50} for tyrosine from 1.38 g/kg to >3.5 and 3 g/kg twice daily, resp. Pretreatment with 80 mg/kg phenobarbital, i.p., or 50 mg/kg 3-methylcholanthrene, i.p., reduced the LD_{50} from 1.38 g/kg to 0.6 and 0.8 g/kg, resp. Mice were also pretreated with two compounds that affect glutathione availability: 100 mg/kg diethylmaleate, i.p., greatly potentiated tyrosine toxicity (LD_{50}, 0.55 g/kg), but 50 mg/kg cysteine, i.p., had the opposite effect (LD_{50}, 2 g/kg). Tyrosine depleted the liver glutathione levels as much as 50%. It is concluded that the liver microsomal drug-metabolizing system is capable of converting tyrosine to a toxic metabolite, perhaps a 2,3-epoxide of tyrosine.

7801 THE EFFECT OF ACETYLCHOLINE ON BILE FLOW.

(Eng.) Nevasaari, K.; Karki, N. T. (Dept. Pharmacology, Univ. Oulu, 90220 Oulu 22, Finland). *Arch. Int. Pharmacodyn. Ther.* 221(2):283-293; 1976.

The effect of acetylcholine (AcC) on bile flow was studied in the isolated perfused liver of male Sprague-Dawley rats. The flow rate of the perfusion medium through the liver was 1.9 ml/g liver/min. The highest AcC concentration (5 x 10^{-4} M) in the medium decreased the perfusate flow rate by 8.7%. Atropine ($< 10^{-4}$ M) inhibited this effect, but physostigmine (1 x 10^{-6} M) and pilocarpine (10^{-7} to 5 x 10^{-4} M) had no effect. However, if physostigmine was added to the medium before AcC, the flow rate was decreased at a lower AcC concentration (1 x 10^{-4} M). About 1 min after the addition of AcC (5 x 10^{-4} M), the bile flow stopped (slow phase), and was followed by an increase (fast phase) and a subsequent return to control levels. The effect was similar to mechanical clamping and opening of the common bile duct. With increasing dose, this biphasic effect is increased, and the smaller the amount of outflowing bile during the slow phase the greater the flow during the fast phase. The effect of AcC was antagonized by atropine but, as with the perfusate, potentiated by physostigmine, so that even 10^{-7} M AcC changed the bile flow. The results suggest that AcC and atropine can pass in a pharmacologically active form from hepatic sinusoidal blood into the biliary tract, affecting it and bile secretion. This may explain the decreased and increased bile flow caused by cholinergic drugs or vagal stimulation.

7802 PRESENCE OR ABSENCE OF INHIBITORS OF CRYSTAL GROWTH IN BILE. 1. EFFECT OF BILE ON THE FORMATION OF CALCIUM PHOSPHATE, A CONSTITUENT OF GALLSTONES.

(Eng.) Sutor, D. J.; Percival, J. M. (Dept. Chemistry, Univ. Coll., Gower St., London, England). *Gut* 17(7):506-510; 1976.

The inhibitory action of bile on the nucleation and crystal growth of calcium phosphate (in the form of apatite) was studied. A solution of 10 ml disodium hydrogen phosphate (0.02 M) and 30 ml water was adjusted to pH 7.0, and 10 ml calcium chloride dihydrate was added. The effect of inhibitors in this system was studied by the addition of sodium citrate or pyrophosphate or samples of bile from gallbladders or common bile ducts to the water. Some samples were ultrafiltered through a filter with a molecular weight cut-off of about 10,000. A micellar solution of sodium taurocholate and egg lecithin was also tested. When the pH of the system was adjusted to 7.0, a precipitate formed, which consisted of a crystalline material with a diffraction pattern like that of apatite, but the *d*-spacing of one of the lines was different. This apatite-like material could be converted to apatite on standing. Small amounts of sodium citrate or pyrophospate (10^{-5} M), could delay the formation of the crystalline phase for about 20 min. In contrast, an added concentration equivalent to 1.8 x 10^{-2} M sodium chloride was necessary for the ionic strength to affect the reaction. Both the gallbladder and common duct biles inhibited formation of the precipitate. In one case, 0.16% gallbladder bile delayed crystallization for 24 min and inhibited the amorphous phase for 18 min. Larger quantities of some samples of gallbladder bile sometimes prevented formation of the initial amorphous precipitate; in one case the solution remained clear for 24 hr. All bile samples caused considerable inhibition in the formation of the precipitate, but equivalent volumes of bile ultrafiltrate usually showed little inhibitory power. A concentration of 1 mM sodium taurocholate and 0.3 mM lecithin in the test system delayed the formation of the crystalline phase for 90 min; concentrations of these substances of 0.6 and 0.2 mM, resp., inhibited this change for 60 min. It is concluded that an inhibitor is present in both the common duct and gallbladder bile, that it probably originates in the liver, and that it has a molecular weight of over 10,000.

7803 EFFECT OF (+)-CATECHIN ON CONJUGATION BY RAT LIVER.

(Eng.) Hargreaves, T.; Piper, R. F. *In: New Trends in the Therapy of Liver Disease. Proceedings of the International Symposium on New Trends in the Therapy of Liver Diseases, Tirrenia June 6-7, 1974.* (New York: S. Karger): pp. 154-163; 1975.

The effect of (+)-catechin on bilirubin and *o*-aminophenol conjugation by rat liver was investigated in male albino Wistar rats. Diazotized ethyl anthranilate was used to measure conjugated bilirubin, and chloroform extraction was used to measure unconjugated bilirubin in rat liver slices. The slices were added to a phosphate, bicarbonate, serum, and bilirubin medium containing (+)-catechin in final concentrations of 0.005, 0.01, 0.05, 0.1, 1, 5, and 10 mM. (+)-Catechin inhibited the formation of conjugated bilirubin in the medium 32-88% with increasing concentration. At 0.1, 1.0, and 10.0 mM (+)-catechin, the conjugated bilirubin content was lower (20.1, 15.0, and 16.9 μg/g liver, resp.) than controls (32.8 μg); although at 0.01 mM the content was higher than controls (42.5 μg). At 10 mM, (+)-catechin decreased the unconjugated bilirubin content (118 versus 195 μg/g for controls). Addition of 2 and 5 mM (+)-catechin to rat liver microsomes in the presence of uridine diphosphate (UDP)-glucuronyltransferase decreased the formation of conjugated bilirubin. A double reciprocal Lineweaver-Burk plot of bilirubin conjugation in the presence and absence of (+)-catechin showed that (+)-catechin competitively inhibits bilirubin conjugation by the enzyme. (+)-Catechin also inhibited *o*-aminophenol conjugation by rat liver.

7804 CYTOCHROME P-450 AND ANIT (α-NAPHTHYL-ISOTHIOCYANATE) INTOXICATION. (Eng.)

Breschi, M. C.; Ducci, M.; Mazzanti, L. *In: New Trends in the Therapy of Liver Disease. Proceedings of the International Symposium on New Trends in the Therapy of Liver Diseases, Tirrenia, June 6-7, 1974.* (New York: S. Karger): pp. 55-61; 1975.

The variation of cytochrome P-450 levels after treatment with iron dextran (Inferon) or Inferon and α-naphthyl isothiocyanate (ANIT) was investigated in male rats. Rats were fed a standard diet alone or with ANIT (1 g/kg food) and/or Inferon (50 mg/kg body weight i.p., twice a week). The animals were sacrificed after 24 and 48 hr (acute intoxication) or after 50, 70, and 90 days (chronic intoxication). Liver weights (g/100 g body weight) varied with duration of treatment: they increased sharply in animals receiving ANIT alone (4, 4, and 4.8 g versus 3.2 g for controls) or ANIT + Inferon (6.3, 5.6, and 6.2 g) (after 50, 70, and 90 days, resp.). At 24 and 48 hr, cytochrome P-450 levels (nM/g liver tissue) increased significantly only in animals treated with ANIT + Interferon (7.3 nM and 8.2 nM versus 6.1 nM for controls). With chronic treatment, the levels were high in animals treated with ANIT alone (12, 9.5, and 8.5 nM after 50, 70, and 90 days, resp.); in animals with ANIT + Interferon, the values were the same as controls (6.1 nM). The peak level was reached on the 50th day and then gradually diminished. After chronic treatment with ANIT alone, there was massive degeneration of the liver; when Inferon was added, it protected the liver from this toxic action. The results show that ANIT enhances the hepatic content of cytochrome P-450 and that this enhancement is inhibited by Inferon.

7805 THE STIMULATORY EFFECT OF FRUCTOSE ON ETHANOL METABOLISM. (Eng.)

Scholz, R.; Schwabe, U.; Plauk, C.; Nohl, H. (Institut fur Physiologische Chemie und Physikalische Biochemie der Universitat Munchen, Goethestrasse 33, D-8000 Munich, W. Germany). *Nutr. Metab.* 18(Suppl. 1):79-92; 1975.

The stimulatory effect of fructose on ethanol (EtOH) oxidation at the cellular level is discussed based on experiments with isolated livers from fasted rats perfused with Krebs-Henseleit bicarbonate buffer in a noncirculating system. EtOH utilization at various concentrations (0.1-2 mM) was gauged in the absence and presence of fructose (4 mM) by the arteriovenous concentration differences and the constant flow rate (5 ml/g/min). The results showed that the rate-limiting step in overall EtOH metabolism is the process of NADH oxidation. Since this limitation is overcome in the presence of fructose, fructose may stimulate EtOH metabolism via an increased oxidation of NADH. The effect of EtOH on fructose metabolism was also investigated. O_2 consumption and glucose, lactate, and pyruvate production were calculated using 4 mM fructose in the presence and absence of 1.2, 2.4, 5, and 15 mM EtOH. In the presence of EtOH, energy-yielding fructolysis was suppressed, but the energy-consuming synthesis of glucose and glycerol was enhanced, and overall fructose metabolism required 10 times more ATP from oxidative phosphorylation. The linear relation found between the extra NADH derived from stimulated EtOH oxidation and the extra ATP utilized for fructose metabolism supports the hypothesis that fructose stimulated EtOH oxidation indirectly, by increasing the energy consumption of the liver. Fructose metabolism and EtOH oxidation must interact at the level of the mitochondrial respiratory chain. The data suggest that maximum rates of NAD-dependent EtOH oxidation depend on the activity of the respiratory chain and, therefore, on the energy requirement of the liver cell in a given metabolic state.

7806 INHIBITION OF HEPATIC UPTAKE OF ALPHA AMINOISOBUTYRIC ACID BY ETHANOL: EFFECTS OF PYRAZOLE AND METABOLITES OF ETHANOL. (Eng.)

Piccirillo, V. J.; Chambers, J. W. (Toxicology Res. Dept., Rohm and Haas, Dublin Lab., 582 W. Goodale St., Columbus, OH). *Res. Commun. Chem. Pathol. Pharmacol.* 13(2):297-308; 1976.

The inhibition of hepatic uptake of α-aminoisobutyric acid (AIB) by ethanol (EtOH) was investigated in isolated perfused Sprague-Dawley rat livers to determine the effects of pyrazole and metabolites of EtOH. After an initial 30-min equilibrium period, 100 μmol of AIB containing 2 μCi of $1\text{-}^{14}C$-AIB was added to the perfusing medium. Uptake of AIB by the liver reached equilibrium 90 min later. Approximately 20% of the labeled AIB was removed from the perfusate in control experiments, but this value was reduced to 11% after the addition of EtOH (200 mg/100 ml). Pyrazole (4 mM) alone was without effect on AIB uptake. When pyrazole was added with EtOH, AIB uptake was similar to control values. Two metabolits of EtOH, 2 mM acetaldehyde and 43 mM acetate, had no effect on AIB uptake. The isolated perfused rat liver produced 7.13 mg of urea nitrogen in control AIB experiments during a 2-hr perfusion period. The amount was reduced to 5.10 mg/2 hr when 200 mg of EtOH was added to the perfusate, but this inhibition was reversed by the addition of pyrazole. The results suggest that the effect of EtOH on AIB uptake is not a direct effect of the alcohol, but due to a metabolic consequence of EtOH oxidation (through an altered $NAD:NADH_2$ ratio).

7807 MOLECULAR INJURY TO MITOCHONDRIA PRODUCED BY ETHANOL AND ACETALDEHYDE. (Eng.)

Cederbaum, A. I.; Rubin, E. (Mount Sinai Sch. Medicine, City Univ. New York, NY 10029). *Biol. Alcohol Alcoholism* 34(11):2045-2051; 1975.

The possible role of mitochondrial function in the increased rate of hepatic ethanol metabolism, seen in rats after chronic ethanol administration, was evaluated by studying energy production and utilization by isolated hepatic mitochondria and the activity of reconstituted shuttles for the transport of reducing equivalents. Male Sprague-Dawley rats were fed for 24-36 days on a liquid diet, with or without ethanol (accounting for 36% of total calories) as an isocaloric replacement of carbohydrate. The mitochondria of ethanol-fed rats had a reduced ability to oxidize various substrates; the oxygen uptake by these mitochondria was reduced by 49%, 50%, 32%, and 11% using glutamate, α-ketoglutarate, succinate, and ascorbate as substrates, resp. Ethanol feeding also affected the energy-dependent Ca^{2+} uptake system of the mitochondria; when substrate or ATP were omitted or when citrinin plus oligomycin were added to inhibit endogenous energy sources, Ca^{2+} uptake was decreased by 90%. The mitochondria displayed reductions in the activity of cytochrome oxidase, succinic dehydrogenase, and α-glycerophosphate oxidase, and the cytochrome content was decreased. There was no change in the mitochondrial yield or concentration in the ethanol-fed rats. The acceleration of ethanol oxidation induced by ethanol feeding was not explained by increases in mitochondrial activity, capacity of shuttles for the transport of reducing equivalents into the mitochondria, or alcohol dehydrogenase activity. The effects of acetaldehyde on mitochondrial functions were found to be similar to those of ethanol consumption, e.g., greater sensitivity of NAD^+-dependent oxygen uptake, selective inhibition of oxidative phosphorylation, and decreased energized Ca^{2+} uptake. *In vitro,* ethanol at concentrations up to 80 mM had no effect on any of the reactions that were effected *in vivo.* The inhibition of electron transport, of energy formation and utilization, and of the reconstituted shuttles suggests the possibility that acetaldehyde may influence the overall metabolism of ethanol.

7808 STUDIES ON POISONOUS METALS. II. EFFECT OF CHELATING AGENTS ON EXCRETION OF CADMIUM THROUGH BILE AND GASTROINTESTINAL MUCOSA IN RATS. (Eng.) Kojima, S.; Kiyozumi, M.; Saito, K. (Faculty Pharmaceutical Sciences, Kumamoto Univ., Kumamoto, Japan). *Chem. Pharm. Bull. (Tokyo)* 24 (1):16-21; 1976.

The excretion of cadmium through the bile and gastrointestinal mucosa after the i.p. administration of cadmium chloride and the effect of the chelating agents EDTA, citric acid, 2,3-dimercapto-1-propanol, L-cysteine, D-cysteine, and DL-penicillamine on its excretion were studied in male Wistar rats. The cumulative biliary excretion of cadmium in a 9-hr period was about 0.85% of the dose (3 mg/kg), and the cumulative content of cadmium in the gastrointestinal lumen was about 0.53% of the dose. The i.v. administration of citric acid (60 mg/kg), D-cysteine (100 mg/kg), and DL-penicillamine (120 mg/kg) increased the mean cumulative biliary excretion to 4.47%, 4.33%, and 2.39% of the dose, resp., in comparison to a control value of 0.95%. The administration of EDTA (90 mg/kg) completely inhibited biliary excretion, and the administration of 2,3-dimercapto-1-propanol (100 mg/kg) reduced biliary excretion to 0.40% of the dose. DL-cysteine had no effect on biliary excretion. None of the chelating agents had a significant effect on the excretion of cadmium via the gastrointestinal mucosa. EDTA, DL-penicillamine, and 2,3-dimercapto-1-propanol produced a decrease in the hepatic cadmium content (20.50%, 47.12%, and 23.51% of dose, resp.) in comparison to that in the untreated control liver (57.79%). Sephadex G-75 chromatography of the bile of rats treated with cadmium, with or without a chelating agent, indicated that cadmium in the bile was bound to several bile components with different molecular weights and that cadmium in the bile of the rats that received cadmium chloride with citric acid, D-cysteine, and DL-penicillamine was largely bound to the substances with a low molecular weight.

7809 MODIFICATIONS OF CITRATE AND ISOCITRATE METABOLISM IN LIVER MITOCHONDRIA OF ETHANOL-FED RATS. (Eng.) Lostanlen, D.; Oudea, M.-C.; Godard-Launay, A.-N.; Oudea, P. (Laboratoire de Pathologie Cellulaire Hepatique, Equipe de Recherche Centre National de la Recherche Scientifique no 334, U.E.R. de Medecine, 1, rue Gaston Veil, 44035-Nantes Cedex, France). *Biochem. Pharmacol.* 24(22): 2061-2068; 1975.

The transports of citrate and isocitrate and the activity of enzymes involved in their metabolism were studied in mitochondria isolated from rat alcoholic fatty livers. Male Sprague-Dawley rats were given a liquid hyperlipidic diet in which ethanol was progressively substituted isocalorically for part of the carbohydrate in weekly stages (25, 37.5 43, and 50 g/l). After 11 weeks on the last dose, the rats were sacrificed and mitochondrial fractions were prepared from the liver. The reduction intramitochondrial pyridine nucleotides following addition of citrate or isocitrate (0.4 to 12 mM), malate (0.6 M), and phosphate (1.2 mM) to the mitochondria was assayed. Upon citrate addition, a 79% increase ($p < 0.001$) in reduction was observed in mitochondria from ethanol-fed rats compared to a contro group. This increase was not observed with isocitrate, possibly because of transport alterations. The efflux of isocitrate exchanged for extramitochondrial citrate was reduced markedly (-50% in ethanol-fed rats), but ^{14}C-citrate penetration into malate-loaded mitochondria was only slightly ($p<0.0$ inhibited and ^{14}C-malate transport was unchanged. Pyridine nucleotide reduction was accelerated when citrate was added to Triton X100-disrupted mitochondria. The following intermitochondrial changes may contribute to this acceleration: increased activit of aconitate hydratase (32%) and NAD-linked isocitrate dehydrogenase (11%), and higher mitochondrial pyridine nucleotide levels (21-35%). The increased utilization of citrate by mitochondria, along with loss of cytosolic ATP-citrate lyase activity in ethanol-fed rats, may depress fatty acid synthesis, in response to an accumulation of triglycerides in the liver cell.

7810 PROTECTING ACTION OF ASPARTATE ON THE HEPATIC CHANGES INDUCED BY D-GALACTOSAMINE (Eng.) Fodor, O.; Schvartz, M.; Suciu, A.; Barbarino, F.; Duca, S.; Lezeu, R. (Clinica III medical str. Iasilor 16, Cluj, Rumania). *Arzneim. Forsch.* 26(5):855-858; 1976.

The protective action of aspartic acid on galactosamine-induced liver changes was studied biochemically in Wistar rats. The rats received galactosa mine (460 mg/kg, i.p.) with or without a simultaneous i.p. injection of potassium aspartate (430 mg); untreated animals served as controls. Between 30 and 120 min after the beginning of perfusion of the isolated livers, the mean SGOT and SGPT levels in the controls were 8.36-14.96 mU/ml and 2.40-7.68 mU/ml, resp. The levels in the galactosamine-treated animals were 10.12-32.12 mU/ml and 7.40-24.34 mU/ml, resp., and the levels in the animals treated with galactosamine plus aspartate were 11.56-18.86 mU/ml and 5.32-13.34 mU/ml, resp. The mean levels of sorbital dehydrogenase in the perfused livers of controls, galactosamine-treated animals, and galactosamine plus aspartate-treated animals were 0.03-2.11 mU/ml, 1.69-4.52 mU/ml, and 0.42-2.26 mU/ml, resp. The lactate/pyruvate ratios in the groups were 10.93-20.43, 8.61-12.64, and 12.31-16.30, resp. The mean level of glycogen in the livers of rats with galactosamine hepatitis (23.31 μM glucose/g fresh liver) was much lower than that in controls (203.99 μM/g, $p<0.001$) and in aspartate-treated animals (89.42 μM/g, $p<0.001$). Methyl green-pyronine staining revealed a stronger pyroninophilia of the cytoplasmic RNA after the administration of aspartate than that in animals treated with galactosamine only. The $NADH_2$-diaphorase reaction was nearly normal in the rats treated with galactosamine plus aspartate, while the reaction in those treated with galactosamine alone indicated exclusive diphormazane formation. The glucose-6-phosphatase, membrane ATPase, and PAS reactions also indicated a protective action of aspartate. The results demonstrate the protective action of aspartate in galactosamine hepatitis. This action may be due to the ability of aspartate to reestablish the cellular deficit of pyridine nucleotides.

7811 THE INHIBITION BY GLUCAGON OF THE VASOCONSTRICTOR ACTIONS OF NORADRENALINE, ANGIOTENSIN AND VASOPRESSIN ON THE HEPATIC ARTERIAL VASCULAR BED OF THE DOG. (Eng.) Richardson, P. D. I.; Withrington, P. G. (Medical Coll. of St. Bartholomew's Hosp., Charterhouse Square, London, EC1M 6BQ, England). *Br. J. Pharmacol.* 57(1):93-102; 1976.

The influence of glucagon on the vasoconstrictor actions of noradrenalin, angiotensin, and vasopressin on the hepatic arterial vascular bed was investigated in anesthetized dogs. The hepatic artery was cannulated and perfused from a femoral artery, with continuous monitoring of blood flow and perfusion pressure. Intra-arterial injections of the vasoconstrictor agents resulted in dose-dependent increases in hepatic arterial vascular resistance (HAVR). A single injection of glucagon (G, 100 μg, intra-arterial) caused a transient fall in HAVR of 20%, while G infusions (25 μg/min) reduced the HAVR by 17%. Single injections of G (100 μg, intra-arterial) reduced the responses to the three vasoconstrictors by 85-90%, with recovery by 8-10 min. Intra-arterial infusions of G (2.5-50 μg/min) reduced the increase in the HAVR in response to the vasoconstrictors throughout the course of the infusion. Intra-arterial infusions of G (25 μg/min) resulted in a shift of the dose-response curves for noradrenalin and angiotensin to the right, but there was no suppression of the maximal response. The dose-response curve for vasopressin during G infusion was also shifted to the right, but there was also a reduction in the maximal response to approximately 50%. Insulin (10 IU) caused a transient reduction in the HAVR and a weak and transient inhibition of the effect of test doses of noradrenalin. It is suggested that the antagonism by G of the vasoconstrictor responses of the hepatic arterial vasculature may be important in protecting against the effects of concomitantly released vasoconstrictors on this bed.

7812 STIMULATION OF THE GLUCURONIC ACID PATHWAY IN ISOLATED RAT LIVER CELLS BY PHENOBARBITAL. (Eng.) Notten, W. R. F.; Henderson, P. Th.; Kuyper, Ch. M. A. (Dept. Pharmacology, Univ. Nijmegen, Nijmegen, Netherlands). *Int. J. Biochem.* 6(10):713-718; 1975.

The effect of phenobarbital (PB) on the synthesis of glycogen and the metabolites uridine diphosphate glucose (UDPG), uridine diphosphate glucuronic acid (UDPGA), D-glucuronic acid, L-ascorbic acid, and D-glucaric acid was investigated in intact parenchymal cells isolated from the male Wistar rat liver. Administration of 0.5 and 1.0 mM PB to suspensions of rat hepatocytes resulted, within 90 min, in an enhanced synthesis of D-glucaric acid [$p<0.05$ (0.5 mM); $p<0.001$ (1.0 mM)], L-ascorbic acid ($p<0.05$, $p<0.001$), and UDPGA ($p<0.05$, at both concentrations). There were no alterations in the *in vitro* activities of UDPG dehydrogenase and UDP glucuronyltransferase within 120 min after PB. At increasing PB concentrations the UDPG level increased significantly [$p<0.01$ (0.5 mM); $p<0.001$ (1.0 mM)], but that of glycogen decreased ($p<0.011$). ^{14}C-labeling experiments showed a lower rate of 1-^{14}C-D-glucose incorporation in the glycogen of PB-treated cells, but an equal increase in specific activities as a function of time was observed in both PB-treated and control cells. This strongly suggests that the lowered glycogen concentration, after treatment with PB, is caused by a decreased synthesis of glycogen, resulting in an enhanced availability of UDPG. It is concluded that a stimulation of the D-glucuronic acid pathway is probably based on an inhibition of glycogen synthesis.

7813 INCREASED BILIARY EXCRETION OF PENTOBARBITAL WITH BILE SALT-INDUCED HEPATIC CHOLERESIS. (Eng.) Knodell, R. G.; Holloway, E. E. (Dept. Hematology, Walter Reed Army Inst. Res., Walter Reed Army Medical Center, Washington, DC 20012). *Biochem. Pharmacol.* 25(14):1682-1684; 1976.

Studies were carried out to determine whether bile salt-induced increases in bile blow might also enhance biliary excretion of pentobarbital. Male Walter Reed rats with external biliary fistulae were perfused with either saline (bile salt-depleted animals) or with 10 or 30 mg/hr of taurocholate. Pentobarbital (40 mg/kg, i.v.) was administered, and bile was collected hourly for 4 hr. Total biliary excretion of pentobarbital and its metabolites in both bile salt-depleted and bile-salt perfused animals showed a linear relation to bile flow. The mean level of biliary pentobarbital excretion in the group perfused with 30 mg/hr of taurocholate (45.91%) was significantly increased compared with that of the bile salt-depleted group (34.35%, $p<0.05$). When the changes in bile flow rate and pentobarbital biliary excretion in the bile salt-perfused animals were compared graphically, statistically significant increases in pentobarbital excretion were seen in both the 10 mg/hr and 30 mg/hr taurocholate-perfused groups. Taurocholate perfusion had no significant effect on the form in which pentobarbital was excreted into bile. These studies show that biliary excretion of pentobarbital and its metabolites is increased by bile salt perfusion. Interdependence between bile flow rates and biliary excretion could explain the increased pentobarbital excretion in response to taurocholate perfusion. If bile salt-induced choleresis can be shown to increase hepatic drug metabolism by depletion of intrahepatic metabolites or to enhance biliary excretion of unchanged parent compounds or active metabolites, it may be a useful means of rapidly manipulating hepatic excretory function.

7814 INTERACTION OF PENTOBARBITAL, DIPHENYLHYDANTOIN AND DIGITOXIN WITH ETHANOL IN THE ISOLATED PERFUSED GUINEA-PIG LIVER. (Eng.)

Haacke, H.; Johnsen, K.; Kolenda, K.-D. (Medizinische Univ.-Klinik Kiel, Metzstr. 53/57, 2300, Kiel, W. Germany). *Arzneim. Forsch.* 26(5):835-839; 1976.

The interaction of ethanol with the metabolism of ^{14}C-pentobarbital, ^{14}C-diphenylhydantoin, and ^{3}H-digitoxin was studied in the isolated perfused guinea pig liver. The mean rate of ethanol oxidation (1.71 mmol/hr) was not altered by the addition of pentobarbital (0.25 mg/100 ml), diphenylhydantoin (0.23 mg/100 ml), or digitoxin (0.0045 mg/100 ml). When ethanol was included in the perfusion, the disappearance of ^{14}C-diphenylhydantoin and ^{14}C-pentobarbital was decreased to 50% of the initial level and the disappearance of ^{3}H-digitoxin was decreased to 20% of the initial level. Ethanol decreased the plasma-chloroform ratio for each of the drugs. Only 3-5% of the radioactivity of ^{14}C-pentobarbital and ^{14}C-diphenylhydantoin was excreted via the bile. Ethanol caused a pronounced accumulation of these two drugs in the liver. Corresponding to the increased radioactivity in the liver, a decrease in the perfusion medium was found. The distribution of radioactivity after the application of ^{3}H-digitoxin was not significantly altered by ethanol, and a large amount of ^{3}H-digitoxin metabolites was excreted in the bile; the radioactivity was concentrated in the bile 200-fold, as compared to the concentration in the perfusion medium. The accumulation of radioactive material in the liver after the application of ^{14}C-pentobarbital and ^{14}C-diphenylhydantoin was accompanied by an increase in the liver tissue-plasma ratio (1.66 versus 2.99 after pentobarbital; 4.00 versus 10.10 after diphenylhydantoin) and by a decrease in the liver-chloroform coefficient I (1.25 versus 0.59 after pentobarbital; 0.132 versus 0.078 after diphenylhydantoin) and the liver-chloroform coefficient II (0.23 versus 0.14 after pentobarbital; 0.023 versus 0.015 after diphenylhydantoin). These results suggest that the accumulation of the drugs in the liver is due to an increase of the lipid solubility of the radioactivity accumulated in the liver. These modifications were not observed with ^{3}H-digitoxin.

7815 EFFECT OF PHOSPHOLIPID ON LIPID METABOLISM IN EXPERIMENTAL FATTY LIVER. (Eng.)

Negishi, I.; Aizawa, Y. (Tokyo Coll. Pharmacy, Sinjuku-ku, Tokyo, Japan). *Chem. Pharm. Bull. (Tokyo)* 23(9):1938-1942; 1975.

The effect of phospholipid on fatty liver induced by orotic acid, carbon tetrachloride (CCl_4), or ethionin was investigated in female Wistar rats. In rats fed a semisynthetic diet supplemented with 1% orotic acid liver glycerides increased 523% (compared with controls), and the contents of liver phospholipid, protein, and serum β-lipoprotein were depressed to 65.1%, 70.2%, and 53%, resp. These effects were restored by the administration of ox brain phospholipid. Liver glycerides in rats given CCl_4 (0.5 ml/100 g, p.o.) or ethionine (100 mg/100 g, i.p.) increased seven- and threefold, resp., and the serum β-lipoprotein was decreased. Phospholipid partially restored these effects. Liver phospholipid was slightly decreased by CCl_4, and liver protein was decreased by CCl_4 and ethionine. Both depressions were unaffected by phospholipids. These results indicate that phospholipid is effective in counteracting the depression of serum β-lipoprotein and liver lipid accumulation by orotic acid, CCl_4, or ethionine.

7816 INHIBITION OF HEPATIC LIPOGENESIS BY ADENINE NUCLEOTIDES. (Eng.)

Harris, R. A.; Yount, R. A. (Dept. Biochemistry, Indiana Univ. Sch. Medicine, Indianapolis, IN 46202). *Lipids* 10(11):673-680; 1975.

The effect of cyclic AMP on the hepatocyte pool size of the noncyclic adenine nucleotides and on hepatic lipogenesis was studied using liver slices and isolated liver cells of male Wistar rats. Incubation of liver slices with 5 mM cyclic AMP resulted in increases in the mean ATP, ADP, AMP, and inorganic phosphate content (0.88, 0.39, 0.14, and 3.9 μmol/g, resp., versus 0.67, 0.24, 0.09, and 3.2 μmol/g in untreated slices). AMP (5 mM) also increased these levels (0.81, 0.28, 0.05, and 5.6 μmol/g, resp., versus 0.61, 0.23, 0.07, and 3.6 μmol/g before treatment). AMP reduced the rate of fatty acid synthesis, from a control level of 52 nmol/min/g to 32, 7, and 8 nmol/min/g with 0.5, 2.5, and 5.0 mM AMP, resp. Cyclic AMP reduced lipogenesis to 18, 4, and 2 nmol/min/g with 0.5, 2.5, and 5.0 mM concentrations. Dibutyryl cyclic AMP (0.05 mM) reduced lipogenesis to 3 nmol/min/g, but did not increase the intracellular adenine nucleotide content. Fatty acid synthesis was also inhibited by ADP, ATP, and adenosine. Similar results were obtained with isolated hepatocytes, although they were more sensitive to AMP, cyclic AMP, ADP, ATP, adenosine, and dibutyryl cyclic AMP; 0.5 mM AMP produced only a 38% inhibition in liver slices, whereas this concentration produced 92% inhibition in the liver cells. Because of the expansion of the adenine nucleotide pool size, high concentrations of cyclic AMP should not be used to investigate the mechanism responsible for hormonal regulation of lipogenesis. AMP was also found to produce a significant increase in the intracellular concentration of cyclic AMP in the isolated liver cells, which may be a factor in the inhibition of lipogenesis by AMP.

7817 CHARACTERISTICS COMMON TO CHOLERETIC INCREMENTS OF BILE INDUCED BY THEOPHYLLINE, GLUCAGON, AND SQ-20009 IN THE DOG. (Eng.)

Barnhart, J. L.; Combes, B. (Univ. Texas Southwestern Medical Sch., Dallas, TX 75235). *Proc. Soc. Exp. Biol. Med.* 150(3):591-596; 1975.

The characteristics of the increased bile formed in response to the administration of theophylline, glucagon, and 1-ethyl-4-(isopropylidenehydrazino)-1H-pyrazole-(3,4-b)-pyridine-5-carboxylic acid (SQ-20009), which also presumably increase the intracellular concentration of cyclic AMP, were studied in dogs. The compounds were administered into one jugular vein, while a mixture of sodium taurocholate (2 mg/ml) and ^{14}C-erythritol was infused into the other. Theophylline (19.9 mg/kg), glucagon (loading dose of 108 µg, followed by a continuous mean infusion of 0.58 µg/kg/min or a single dose of 2.2 µg/kg), and SQ-20009 (4.7 mg/kg or a loading dose of 2 mg followed by a constant mean infusion of 0.073 mg/kg/min) all caused significant increases in bile flow; the mean change in bile flow for each compound was 0.111, 0.083, and 0.055 ml/min, resp. Choleresis was accompanied by proportionate increases in ^{14}C-erythritol clearance in bile. The average ratio of change in erythritol clearance to change in bile flow for each compound was: theophylline, 1.12; glucagon, 1.07; and SQ-20009, 0.85. None of these means was statistically significantly different from 1.0 or from any other. Bile salt excretion decreased by 1.5 µmol/min on the average in dogs receiving theophylline and did not change significantly in animals given the other compounds. The mean concentrations of sodium, potassium, chloride, and bicarbonate ions were measured in bile taken during the control and treatment periods. The electrolyte composition was practically the same after treatment with each compound. These observations support the important role of cyclic AMP in the sequence of events leading to the formation of the bile salt-independent fraction of canalicular bile in the dog.

7818 INFLUENCE OF EXPERIMENTAL, PROXIMAL AND DISTAL BILE-FLOW OBSTRUCTION ON ACTIVITY AND NUMBER OF ISOENZYME AMYLASE IN SERUM AND URINE OF RATS. (Eng.)

Miholjcic, M.; Radovanovic, J.; Selak, I. (Dept. Physiology and Biochemistry, Univ. Sarajevo, Sarajevo, Yugoslavia). *Folia Med.* 9:161-172; 1974.

The influence of laparotomy and ligation of the proximal and distal bile flows on rat serum and urine amylase activity was investigated. Laparotomy did not cause any significant changes in urine and serum amylase activity. Ligation of the proximal end of the bile flow did not produce any significant changes in serum amylase activity on day 1. From days 3 to 16, the activity increased about twice as much ($p<0.001$). There was also a significant increase in urine activity from the 1st ($p<0.05$) to the 8th day ($p<0.001$), but on day 16 this activity was less than that of controls. Distal ligation caused a significant increase in serum activity from days 3 to 16 ($p<0.001$). The urine activity differed: up to 5 days it was increased and was greater than controls ($p<0.001$), but from 8 to 16 days, it became significantly lower ($p<0.001$) than controls. The results show that there is no difference in serum and urine amylase activity of laparotomized rats or rats with ligatures of the distal or proximal end of the bile flow.

7819 EFFECT OF GAMMA RADIATION ON THE ENZYMATIC ACTIVITY OF CELL ORGANELLES OF LIVER AND EPITHELIUM OF SMALL INTESTINE IN RABBITS. (Eng.)

Kanski, M.; Pilek, K.; Zachara, B.; Kosiorek, B. (Zaklad Biochemii, Pl 9 Maja 1, 90-647 Lodz, Poland). *Pol. Med. Sci. Hist. Bull.* 15/3(5/6):607-612; 1975.

The protein content and enzyme marker activity were determined in the homogenate and $140,000 \times g$ supernatant of rabbit liver and intestinal epithelium on days 1, 3, 6, 9, 15, and 30 after a single exposure to ^{60}Co irradiation (550 rads). The protein content of liver homogenates peaked at 145% of controls by the 3rd to 6th day, and in intestinal epithelium, it was 2.5 times normal on the 3rd day. Negligible changes in protein were observed in the supernatants. Both liver and intestinal homogenates had a maximal fall in succinate dehydrogenase activity of the 1st day, with a return to normal values by day 9 in the liver and day 15 in the intestine. Glucose-6-phosphatase fell slightly in liver homogenates and supernatants in the 1st and 3rd day after irradiation and was still low at 30 days. A marked decrease in this enzyme activity (to 47%) was noted in intestinal homogenates after 1 day, and this slowly rose to normal values by day 30. Negligible changes were seen in the intestinal supernatant. The only change in acid phosphatase was a negligible decrease in the homogenate of the intestinal epithelium on the 3rd day. Uricase was decreased in homogenates and supernatants of both tissues on the 1st day; the peak depression of uricase activity in intestinal homogenates was observed on day 3. 5-Nucleotidase was normal in both homogenates and supernatants of liver, but a striking and persistent increase in its activity occurred in intestinal homogenates; changes in the intestinal supernatant were negligible. Alkaline phosphatase increased on the 1st day in liver homogenates and supernatants and reached a maximum on the 6th day, with gradual normalization by day 30. Alkaline phosphatase activity in the intestinal homogenates increased considerably from day 1 on and remained elevated on day 30. This enzyme did not greatly change in the intestinal supernatants.

7820 THE MECHANISM OF THE EFFECT OF INCREASED BILIARY PRESSURE ON HEPATIC CIRCULATION. (Eng.)

Szabo, G.; Jakab, F.; Magyar, Z. (Natl. Inst. Traumatology, H-1430 Budapest, Mezo Imre ut 17, Hungary). *Acta Med. Acad. Sci. Hung.* 31(3/4):241-250; 1974.

The hypothesis that the increase in hepatic arterial blood flow seen after the occlusion of the common duct and the resultant increase in biliary pressure is a myogenic reaction was tested in dogs with common duct cannulae. The sudden experimental increase in biliary pressure to 40 mm Hg (produced by infusing physiological saline into the common duct) resulted in an immediate 39% increase in the hepatic arterial blood flow. Concomitantly, the portal venous flow decreased by 9.5%. When biliary pressure was raised gradually by increments of 5 mm Hg at 5-min intervals, there was little change in hepatic arterial flow when the biliary pressure was under 20 mm Hg. A sudden increase in flow occurred between 20 and 35 mm Hg. When the common duct pressure was raised by saline infusion, hepatic arterial flow increased abruptly, reaching a maximum value in about 30 sec, and remained at this level during the 5-15 min observation time. When biliary pressure dropped to zero, hepatic arterial flow returned slowly to the control value (5-10 min). When dextran or serum was used to increase common duct pressure in place of saline, hepatic arterial flow increased to a level similar to that seen with saline, reaching a maximum in 0.5-1 min; the flow decreased rapidly at sustained high duct pressure, attaining the control value in less than 3 min. The effect of increased biliary pressure was unchanged by i.v. injections of phentolamine (0.2-0.4 mg/kg), phenoxybenzamine (2 mg/kg), propranolone (0.2-0.3 mg/kg), or atropine (0.5-1.0 mg/kg). The vasodilatory response was elicited even during vasoconstriction induced by norepinephrine (10 μg/min). It is concluded that the increase in hepatic arterial flow is caused by a myogenic arteriolar vasodilatation, which is triggered by the decrease in effective vascular transmural pressure.

7821 INDUCTION OF MICROSOMAL MONOXYGENASE OF THE LIVER IN EXPERIMENTAL CHOLESTASIS. (Rus.) Zakharova, N. E.; Mordvinov, V. A.; Tsyrlov, I. B.; Lyakhovich, V. V. (Inst. Experimental Clinical Medicine, USSR Acad. Medical Sciences, Siberian Branch, Novosibirsk, USSR). *Biull. Eksp. Biol. Med.* 81(4):418-420; 1976.

Microsomal monoxygenase induction by phenobarbital in the absence of substrate binding sites in cytochrome P-450 active centers was studied in male Wistar rats. Experimental cholestasis was produced by the ligation of the bile duct. The animals received sodium phenobarbital (100 mg/kg/day) on days 4, 5, and 6 after operation. Sham-operated rats were used as controls. The cholestasis was accompanied by the accumulation of hydroxylated cholesterol metabolites having detergent characteristics, which destroyed the substrate binding site for phenobarbital in the P-450 molecule. Consequently, the primary conjugation and metabolism of phenobarbital by the enzyme was impossible. Pronounced induction of microsomal monoxygenases by phenobarbital was observed. The activation of *de novo* microsomal protein synthesis is assumed to be effected by the phenobarbital molecule proper, and not by the products of its primary hydroxylation in the microsomes.

7822 MOUSE HEPATIC NEOPLASIA. SIGNIFICANCE A EXTRAPOLATION TO MAN. (Eng.) Newberne, J. W. *In: Mouse Hepatic Neoplasia. Proceedings o a Workshop held at the H.T.S. Management Centre, L End, High Wycombe, (Great Britain), 12-17 May 1974* (New York: Elsevier Scientific Publishing Company pp. 165-177; 1975.

The problem of the response of the mouse liver to chemical agents is discussed. In this workshop, th participants were unable to develop a consensus on a precise distinction between benign and malignant neoplasms in the mouse liver, and they were unable define objective criteria essential to such judgements. Objective criteria have not been defined that would clearly indicate whether the mouse liver accurately reflects the general carcinogenicity of a compound. The utility of the mouse for purposes of routine screening of chemicals for carcinogenic potential is, therefore, highly questionable. It i suggested that strong consideration be given to deleting the mouse as a routine test animal for such purposes, although the species should definitely be retained as a useful system for studies in experimental carcinogenesis. A reliable procedure for assigning levels of significance (relative safety, risk factor) to carcinogenic responses should be developed. It is suggested that such a system might incorporate as one facet, the statistical treatment of data. This would require that a carcinogenic dose be defined and that the dose-response concept be accepted for carcinogenicity evaluation as it is for other types of toxicological investigations.

7823 ASSOCIATION OF MOUSE LIVER ADENOSINE 3': CYCLIC MONOPHOSPHATE (CYCLIC AMP) LEVELS WITH HISTOCOMPATIBILITY-2 GENOTYPE. (Eng.) Meruel D.; Edidin, M. (Dept. Biology, Johns Hopkins Univ., Baltimore, MD 21218). *Proc. Natl. Acad. Sci. USA* 72(7):2644-2648; 1975.

SECRETION AND METABOLISM

Intestine

7855 ISOLATION AND CHARACTERIZATION OF IRON-BINDING PROTEINS FROM RAT INTESTINAL MUCOSA. (Eng.) Huebers, H.; Huebers, E.; Rummel, W.; Crichton, R. R. (Institut fur Pharmakologie und Toxikologie, Universitat des Saarlandes, D-6650 Homburg Saar, W. Germany). *Eur. J. Biochem.* 66(3):447-455; 1976.

Two iron-binding proteins were isolated from the rat intestinal mucosa and characterized as mucosal ferritin and mucosal transferrin. Polyacrylamide gel electrophoresis revealed that rat mucosal, spleen, and liver ferritin migrated to approximately the same extent and was less acidic than horse ferritin. Both mucosal and plasma transferrin migrated similarly and gave two bands. Isoelectric focusing of rat mucosal ferritin gave a single band with an isoelectric point (IEP) of 5.1. The IEP of spleen and liver ferritin was 5.2. Plasma transferrin gave two bands (IEP 5.7 and 5.6), as did mucosal transferrin (IEP 5.5, 5.3). The molecular weights of spleen, liver, and mucosal ferritin were 19,300, 19,000, and 19,200, esp., while the molecular weights of plasma and mu-osal transferrin were 77,000 and 76,000, resp. The edimentation constants for spleen, liver, and mucosal erritin were 17.6, 17.3, and 17.5, resp. The iron ontent of mucosal ferritin (550 atoms/molecule) as considerably less than that of the spleen and iver ferritins (3,300 and 3,000 atoms/molecule, esp.). Isopycnic density-gradient centrifugation f the mucosal ferritin demonstrated a population of olecules with an iron content of 450-800 iron atoms/olecule and little full ferritin. Unlike plasma ransferrin, mucosal transferrin could be labeled with ^{9}Fe only when incubated with the iron salt and a mu-osal homogenate. Immunological analysis of the three at ferritins with horse spleen ferritin indicated artial cross reaction with each of the proteins. at mucosal transferrin strongly cross-reacted with ntiserum prepared in rabbits against rat serum trans-errin. The amino acid composition of the rat fer-itins varied considerably, with the most marked dif-erences in tyrosine, glutamic acid, threonine, serine, eucine, and arginine. This study confirms that the ucosal iron-binding proteins are tissue-specific ransferrin and ferritin; transferrin is important or iron transfer through the mucosal cells in iron eficiency, while ferritin is the iron-binding inter-ediate that participates in the slow phase of iron osorption.

356 SUBSTRATE INTERACTIONS ON THE INTESTINAL MUCOSA: A CONCEPT FOR THE REGULATION OF NTESTINAL DIGESTION. (Eng.) Ugolev, A. M.; Gruzd-ov, A. A.; De Laey, P.; Egorova, V. V.; Iezuitova, . N.; Koltushkina, G. G.; Timofeeva, N. M.; Tulya-anova, E. Ch.; Tsvetkova, V. A.; Chernyakhovskaya, . Yu.; Shcherbakov, G. G. (I.P. Pavlov Inst. Phy-iology, Academy Sciences USSR, Leningrad, USSR). *r. J. Nutr.* 34(2):205-220; 1975.

he hydrolysis of glycyl-L-leucine, glycyl-L-tyrosine, ributyrin, sucrose, maltose, soluble starch, and α-nd β-glycerophosphates by everted segments of rat ntestine was estimated separately or in combination. here was a significant interaction between differ-nt substrates, which affected their digestion. Two ypes of interaction were identified. In the first ype, products of hydrolysis affected the hydrolysis f homologous substances; e.g, methionine and ala-ine inhibited glycyl-L-leucine hydrolysis, and mal-ose reduced glucoamylase (α-1,4-glucan glucohydro-ase) activity (intracatenary interactions). In the econd type of interaction, the products of hydroly-is interfered with the hydrolysis of a different roup of substances; e.g., tributyrin inhibited di-eptidase (glycyl-L-leucine hydrolase) and alkaline hosphatase, and glycyl-L-leucine interfered with he activity of the latter enzyme (intercatenary nteractions). Mechanisms of interactions were uggested by the results of a comparison of the ex-ent of inhibition or activation of glycyl-L-leucine ydrolase and alkaline phosphatase *in situ* in evert-d intestinal segments or after solubilization with apain or Triton X-100 and different treatments nown to affect allosteric sites of these enzymes. ributyrin and dipeptides acted on alkaline phospha-ase as allosteric regulators. A discontinuity of the Arrhenius plot suggested the existence of different enzyme conformations that were rearranged by tributyrin. Substrate interactions in digestion were found in adult rat, cat, rabbit, and hen. Substantial differences were found between classes (Aves and Mammalia), between orders (rodents, lagomorphs, and carnovores), and between age groups within an animal strain. These interactions are thought to be involved in the coordination of digestion with intestinal absorption and to regulate the time and site of subsequent hydrolysis.

7857 DIFFERENTIAL SENSITIVITY OF INTESTINAL BRUSH BORDER ENZYMES TO PANCREATIC AND LYSOSOMAL PROTEASES. (Eng.) Seetharam, B.; Grimme, N.; Goodwin, C.; Alpers, D. H. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *Life Sci.* 18(1):89-95; 1976.

The degradation of enzymes of the brush border membranes of human small intestine by proteolytic enzymes was studied. The isolated brush border membranes were prepared from autopsy material within 10 hr of death. At pH 7, free trehalase was degraded by bovine pancreatic trypsin at the same rate as membrane-bound trehalase, whereas elastase had more effect on solubilized trehalase. Trypsin, chymotrypsin, and elastase had similar effects on both free and bound sucrase, which was the most sensitive of the hydrolases to the action of the proteolytic enzymes. Alkaline phosphatase, bound or free, was the most resistant of the hydrolases to proteolytic degradation. It is concluded that solubilization from the membrane does not enhance the susceptibility of the hydrolases to proteolysis. Chymotrypsin had little effect on sucrase and alkaline phosphatase at pH 5, while trehalase was inactivated by chymotrypsin at acidic pH and was less susceptible at pH 7 and 8. Alkaline phosphatase was rather stable in face of chymotrypsin at acid pH; at pH 7 and 8, only about 20% of its activity was lost. When brush border membrane was exposed to varying concentrations of rat liver lysosomal extracts at pH 5, alkaline phosphatase was not inactivated, sucrase was very slightly affected, and approximately 50% of the trehalase activity was lost. The degradation of trehalase was time dependent and approximated first-order kinetics. Boiled lysosomal extracts were inactive against trehalase, suggesting an enzymatic reaction. It is suggested that the brush border membrane of the intestine is subject to proteolysis by pancreatic enzymes from the external cell surface and by lysosomal proteases within the cell.

7858 METHIONINE METABOLISM IN MAMMALS: S-ADENOSYLHOMOCYSTEINE HYDROLASE IN RAT INTESTINAL MUCOSA. (Eng.) Finkelstein, J. D.; Harris, B. (Veterans Admin. Hosp., Washington, DC). *Arch. Biochem. Biophys.* 171(1):282-286; 1975.

In a previous experiment, *S*-adenosylhomocysteine hydrolase could not be detected in extracts of rat small intestinal mucosa, but a heat-labile factor that inhibited hepatic *S*-adenosylhomocysteine hydrolase was detected in this tissue. The present experiments were carried out to test the hypothesis that inhibition results from the consumption of the substrate adenosine by adenosine deaminase present in the crude intestinal preparations. Enzyme activity was assayed by measuring the rate of *S*-adenosyl-L-homocysteine (AdoHcy) synthesis. When the adenosine deaminase inhibitor, 6-methylaminopurine-9-ribofuranoside (MAPR, 1 mM) was added to the small intestinal extracts from Sprague-Dawley rats, a compound chromatographically inseparable from authentic AdoHcy was synthesized as a linear function of the concentration of the intestinal extract. AdoHcy synthesis was also demonstrated in the absence of MAPR by the intestinal protein fraction that is precipitated between 40 and 60% saturation with ammonium sulfate. However, this fraction retained significant adenosine deaminase, and the synthesis of AdoHcy increased from 7.6 to 354 nmol/30 min when MAPR was added. The rate of disappearance of AdoHcy (15 μM) incubated with intestinal extract was proportional to the volume of intestinal extract added (0.01-0.1 ml). The rate of disappearance of AdoHcy was also proportional to the concentration of substrate; the consumption of substrate was almost complete at concentrations below 5 μM. By employing the reaction velocities at the higher substrate concentrations (10-90 μM), a tentative value of 33 M for the K_m was obtained. The products of AdoHcy hydrolysis were identified; the sulfur amino acid portion yielded homocysteine. In the absence of any inhibitor, the purine moiety was degraded to uric acid. The results indicate that intestinal mucosa contains an AdoHcy hydrolase that possesses many of the properties previously found for the liver enzyme. No evidence for an alternative reaction for the catabolism of AdoHcy was found.

7859 STRUCTURE-FUNCTION STUDIES OF THE INTERACTION OF THE HORMONALLY ACTIVE FORM OF VITAMIN D_3, $1\alpha,25$-DIHYDROXY-VITAMIN D_3, WITH THE INTESTINE.

(Eng.) Norman, A. W.; Procsal, D. A.; Okamura, W. H.; Wing, R. M. (Dept. Biochemistry, Univ. California, Riverside, CA 95202). *J. Steroid Biochem.* 6(3/4):461-467; 1975.

Recent developments in the chemistry, metabolism, and mechanism of action of vitamin D are reviewed. The steroid cholecalciferol, or vitamin D_3, undergoes a successive two-step hydroxylation, first in the liver to give 25-hydroxy-D_3, and then in the kidney to produce $1\alpha,25$-dihydroxy-D_3 ($1\alpha,25\text{-(OH)}_2\text{-}D_3$), the biologically active form. The biological response to $1\alpha,25\text{-(OH)}_2\text{-}D_3$ in target tissues (intestine, bone, and possibly kidney) is a consequence of association with cytoplasmic and nuclear receptors. A steroid competition assay was devised using receptors present in intestinal chromatin. A comparison of the relative competition in the assay and biological activity of several analogs had defined some of the essential structural elements required for vitamin D activity. These structure-function relationships are discussed with particular emphasis on the A-ring conformation. The A ring of these seco-steroids consists of a pair of rapidly equilibrating chair conformers. As a consequence, different chair conformations produce different orientations of substituent groups in the A ring. It is proposed that the 1α-hydroxyl of $1\alpha,25\text{-(OH)}_2\text{-}D_3$ or its geometric equivalent in analogs must occupy the equatorial orientation for optimization of biological activity. Data are presented that support the conclusion that $1\alpha,25\text{-(OH)}_2\text{-}D_3$ must first bind with a specific receptor protein present in the cytoplasm of target cells; this is followed by movement into the nuclei, where the steroid associated with a finite number of specific chromatin receptor sites.

7860 BILE ACID STIMULATION OF COLONIC ADENYLATE CYCLASE AND SECRETION IN THE RABBIT.

(Eng Conley, D. R.; Coyne, M. J.; Bonorris, G. G.; Chung, A.; Schoenfield, L. J. (Knoxville Gastroenterology Group, Assoc., Suite 100, Physicians Office Building 1928 Alcoa Highway, Knoxville, TN 37920). *Am. J. Dig. Dis.* 21(6):453-458; 1976.

The *in vivo* effects of various doses of deoxycholic acid (DCA) on adenylate cyclase (AC) activity and net secretion in the rabbit colon were investigated in female New Zealand white rabbits. Four loops, separated from one another by double ligature were constructed in the ascending colon, and 1 ml of test or control solution was injected into the lumen of each loop through the antimesenteric border. The test solutions were 10 mM dibutyryl cyclic 3',5'-AMP and 1, 2, 4, 6, and 8 mM DCA. Significant ($p<0.01$) secretory responses were produced with 4, 6, and 8 m DCA (0.26, 1.2, and 1.9 ml/cm, resp.) compared to co trols (0.13 ml/cm). The increases in AC activity fo 1, 2, 4, 6, and 8 mM DCA were 134%, 161%, 205%, 236% and 401% of control values, resp., all significantly greater than control ($p<0.01$) except the 1-mM value. At 8 mM, the activity was 126 pmol cAMP/mg protein/min. The AC activity and colonic secretion correlated directly ($p<0.02$) at doses of 4, 6, and 8 mM DCA. There was a significant depression of phosphodiesterase (PDE) activity ($p<0.01$) only with 8 mM DC (to 184.0 pmol/mg/min versus 240.3 pmol/mg/min for controls). Dibutyryl cAMP also produced significant ($p<0.01$) colonic loop secretion (1.58 ml/cm) when compared to controls. It is concluded that the cAMP system is strongly implicated in the mechanism of DCA stimulation of colonic secretion. This mechanis may be operative in the pathogenesis of bile acid-induced diarrhea in man.

7861 ION TRANSPORT CHANGES DURING CALCITONIN-INDUCED INTESTINAL SECRETION IN MAN.

(Eng.) Gray, T. K.; Brannan, P.; Juan, D.; Morowski, S. G.; Fordtran, J. S. (Univ. Texas Health Science Center, Southwestern Medical Sch., Dallas, TX). *Gastroenterology* 71(3):392-398; 1976.

Water and electrolyte secretion by the jejunum and ileum were studied in normal human volunteers during i.v. infusion of synthetic salmon calcitonin (SCT) or synthetic human calcitonin (HCT). At 0.5 μg/kg/hr, HCT reduced water and electrolyte absorption rates by the jejunum, but only the change in potassium absorption was significant ($p=0.025$). At 1.0 and 2.5 μg/kg/hr, the secretion of water and elec-

:olytes was approximately equal. The serum calcium oncentration did not significantly change during ny of the infusion rates. At 1 μg/kg/hr, HCT did ot significantly alter the potential difference beween peripheral venous blood and luminal contents. uring the infusion, sodium and chloride were secreted nto the jejunal lumen; the chloride secretion was gainst an electrochemical gradient. The rate of ater and electrolyte absorption by the jejunum was educed during infusion of SCT when the lumen conained glucose (100 mM), but secretion was not inuced. In the ileum, SCT infusion caused the secreion of water, sodium, potassium, chloride, and icarbonate. In the jejunum, SCT infusion reduced he net sodium absorption by reducing the flux rate f sodium out of the lumen. In the ileum, the change rom net sodium absorption to net sodium secretion as almost entirely the result of a reduction in the lux out of the lumen, from 27.5 to 15.8 mEq/hr/30 cm. here was no significant change in the sodium uniirectional flux rate into the lumen. In most cases, CT caused a fall in the pCO_2 of the luminal contents ollected from the distal end of the test segment hen infusion solutions contained bicarbonate. Arerial pCO_2 did not change. It is concluded that alcitonin induces active chloride secretion and inibits active sodium absorption and that bicarbonate bsorption is reduced by virtue of secretion of hyroxyl ions. Since higher than physiological levels f calcitonin were required for induction of intestinl secretion, calcitonin probably does not mediate pontaneous variations of intestinal transport in ormal individuals. It may be a cause of severe ecretory diarrhea in certain disease states (medulary carcinoma of the thyroid) associated with high lasma calcitonin concentrations.

'862 EFFECT OF PENICILLIN ON THE SUCCESSION, ATTACHMENT, AND MORPHOLOGY OF SEGMENTED, 'ILAMENTOUS MICROBES IN THE MURINE SMALL BOWEL.

Eng.) Davis, C. P.; Savage, D. C. (Dept. Medical licrobiology Surgery, Univ. Wisconsin, Madison, WI 53706). *Infect. Immun.* 13(1):180-188; 1976.

The attachment and morphology of a segmented filamentous prokaryote found in the murine small bowel were studied by scanning electron microscopy, and the effects of penicillin on the colonization, morphology, and attachment of these microbes were studied with scanning, transmission, and light microscopy. C57Bl/6St Crl Br and COBS CD-1 (ICR) BR mice and ARS/Sprague-Dawley rats were used. In the mice, many microbes were attached to the epithelial villous cells near the ileocecal valve. There are few microbes in the proximal ileum, and none of the animals showed any microbes on jejunal pieces taken within 8 cm of the pyloric sphincter. The length of the microbes varied from about 1 to 100 cm. About twothirds of the length of the distal villi of both mice and rats was populated by the microbes. Although disruption of the microvillus border was observed in the immediate area of attachment, the great majority of microvillus borders were intact in both mice and rats. Microbes were attached to exfoliating epithelial cells. They were not found in any of 20 mice that received penicillin (0.6 g/l) in the drinking water for 7 days or in any of 50 animals treated with penicillin and then given acidified water (0.001 HCl) for 17 days. Recolonization occurred 32-35 days after the penicillin treatment was stopped. In animals fed an ileal homogenate 18 days after penicillin treatment, recolonization occurred about 28 to 32 days after penicillin treatment ended. Within 3-5 hr after rats were given penicillin, the morphology of the microbes was changed. Their external surfaces were wrinkled or broken, and vacated and partially vacated attachment sites were observed. Almost all organisms disappeared from murine ilea within 10 hr of penicillin treatment. Removal of the attachment site and resynthesis of lumenal membrane microvilli by the epithelial cells were suggested by the presence of Golgi and membranebound vesicles adjacent to the attachment site. It seems likely that the epithelial cells replace the attachment site with either lumenal membrane or microvilli or both.

7863 THE EFFECTS OF SODIUM RICINOLEATE ON SMALL INTESTINAL FUNCTION AND STRUCTURE. (Eng.)

Cline, W. S.; Lorenzsonn, V.; Benz, L.; Bass, P.; Olsen, W. A. (Gastroenterology Res. Lab., Madison Veterans Admin. Hosp., Madison, WI 53706). *J. Clin. Invest.* 58(2):380-390; 1976.

Sodium ricinoleate-induced secretion was investigated *in vivo* in the perfused small intestine of male Syrian Golden hamsters. At 8 mM, ricinoleate resulted in secretion of water and Na ($p<0.01$ compared to controls), a 12-fold increase in intestinal clearance of inulin, and a less-striking but significant enhancement of dextran clearance. At 2 mM, ricinoleate did not affect water or Na transport or alter intestinal permeability. Ricinoleate-induced intestinal secretion was also accompanied by a threefold increased mucosal cell exfoliation, as measured by the appearance of DNA in the perfusate, and by apparent injury to epithelial cell membranes, as judged by measurement of sucrase activity and phospholipid in cell-free aliquots of luminal fluid. Light and electron microscopy demonstrated that 8 mM ricinoleate caused substantial mucosal architectural changes, villus shortening, and injury to epithelial cells at the villus tips. In contrast, cholera enterotoxin caused marked secretion of Na and water, presumably by a cyclic AMP mechanism, but did not alter inulin clearance or enchance DNA or sucrase appearance in the lumen. These studies suggest that at least a component of ricinoleateinduced intestinal secretion is related to structural alterations of the mucosa.

7864 EFFECT OF TRIIODOTHYRONINE ON HUMAN JEJUNAL GLYCOLYTIC ENZYMES. (Eng.)

Lufkin, E. G.; Taunton, O. D.; Stifel, F. B.; Hofeldt, F. D.; Wrensch, M. R.; Hagler, L.; Herman, R. H. (Mayo Graduate Sch. Medicine, Rochester, MN 55901). *Proc. Soc. Exp. Biol. Med.* 150(2):410-413; 1975.

To determine the effect of thyroid hormone on human intestinal enzymes, four normal and three hypothyroid men received tri-iodothyronine (T_3, 100 μg/8 hr, p.o.) together with different carbohydrate diets. The carbohydrate-free diet contained 70% of the calories as fat and 30% as protein and was given during periods 2 and 6 (covering 3 days) of the study. Glucose and fructose diets, with 50% of the calories as sugar, 30% as fat, and 20% as protein, were given during periods 3 and 7 (3 days) and 4 and 8 (3 days) of the study, resp. During periods 1 and 5 (1 day), the subjects fasted. T_3 was given during periods 5-8. In the normal subjects, pyruvate kinase, fructose-1-phosphate aldolase, and fructose-1,6-diphosphate aldolase showed adaptive increases in activity as the diet was sequentially changed from fasting to carbohydrate-free, glucose, and fructose. The opposite effect was seen for fructose diphosphatase, whose activity was highest with fasting, declined with the carbohydrate-free and glucose diets, and was intermediate with the fructose diet. T_3 caused increased jejunal pyruvate kinase and decreased fructose diphosphatase activity during the fasting, carbohydrate-free, and glucose diets, compared to these same periods without T_3. T_3 showed no interaction with the dietary effect on these enzymes during fructose feeding. Fructose-1,6-diphosphate aldolase and fructose-1-phosphate aldolase were decreased during fructose feeding and T_3 administration. These results indicate that T_3 interacts with dietary carbohydrates to affect human jejunal glycolytic and gluconeogenic enzyme activities. In the hypothyroid men, pyruvate kinase activities were decreased and fructose diphosphatase activities were increased during the administration of all diets. T_3 restored enzyme activities to normal only occasionally.

7865 INFLUENCE OF STAPHYLOCOCCAL ENTEROTOXIN ON WATER AND ELECTROLYTE TRANSPORT IN THE SMALL INTESTINE.

(Eng.) Elias, J.; Shields, R. (Dept. Surgery, Univ. Liverpool, Liverpool, England). *Gut* 17(7):527-535; 1976.

The direct and indirect effects of staphylococcal enterotoxins A and C on the flux of water, sodium, and potassium were studied in paired jejunal or ileal Thiry-Vella fistulae in dogs. When the two toxins were studied separately, they produced responses that were not significantly different; thereafter, the toxins were pooled and studied together. After the administration of toxin in the jejunum, the net absorption rates of water and sodium were reduced from initial mean values of 2.7 ml/10 min and 457 μEq/10 min, resp., to values of 0.6 ml/10 min and 100 μEq/10 min, resp. There was a net secretion of potassium (1 μEq/10 min) after the administration of toxin, whereas potassium was absorbed at a rate of 7 μEq/10 min before this. The mean rate of water movement out of the lumen was 10.4 ml/10 min, and 7.6 ml/10 min into the lumen. The mean flux of sodium out of the lumen was 951 μEq/10 min, and 490 μEq/10 min, into the lumen. The mean potassium flux was 26 μEq/10 min out of the lumen, and 18 μEq/10 min into the lumen. After the administration of toxin, the mean fluxes out of the lumen were significantly lower (7.6 ml/10 min, 601 μEq/10 min, and 19 μEq/10 min for water, sodium, and potassium, resp.), whereas the fluxes into the lumen for each substance were not significantly changed. Similar results were obtained in the ileum. Lower doses of toxin (5 and 10 μg) did not produce as marked an effect on net transport and flux as did higher doses (20, 40, and 80 μg), but otherwise the influence of toxin on absorption was not dose-related. Absorption tests were carried out in a single loop into which either toxin or control solution had been instilled, and in the paired fistula to determine if enterotoxin could affect absorption elsewhere in the intestine. The effect of enterotoxin on the remote intestine was demonstrated, and this effect was more obvious in the ileum than in the jejunum. The local response was greater than that produced at a distance. These observations suggest that the main action of the enterotoxin is a direct one upon the bowel to which it is applied.

7866 FUNCTIONAL AND METABOLIC CHANGES OF THE MUCOSA DURING OBSTRUCTION OF THE SMALL INTESTINE OF THE RAT.

(Ger.) Merkle, P.; Bindewald, H.; Breitig, D. (Abteilung fur Allgemeine Chirurgie der Universitat, D-900 Ulm-Safranberg, Steinhovelstr. 9, W. Germany). *Langenbecks Arch. Chir.* 338(4):291-297 1975.

The pathogenesis of restricted absorption in the obstructed small intestine is examined. The small bowel of fasted male SPF Wistar rats was ligated behind the ligament of Treitz, and the absorption of ^{14}C-glucose and ^{3}H-antipyrine (TAT) mucosal ultrastructure, and enzyme activity were measured. Postsurgical survival was 80% at 48 hr. The experimental group (EG) displayed cloudy intraperitoneal exudate, distension of the proximal gastroduodenum, and hypoxia of the distal bowel. After 24 hr, 35% of the ^{3}H-antipyrine had been absorbed by the test group (the value was 57% for the control group), and after 48 hr, 32% had been absorbed (the value was 62% for the control group). After 24 hr, 57% of the glucose was absorbed by the test group (the value was 70% for the control group), and after 48 hr, 35% had been absorbed (the value was 67% for the control group). At 48 hr, the activities of sorbitol dehydrogenase and SGOT were diminished to 0.78 and 154 mU/mg protein compared to 0.9 and 191.7 in the control group. Glucose-6-phosphate dehydrogenase and LDH increased to 34.1 and 2,895 mU/mg protein, resp., in the test group, compared to 25.5 and 2,227 in the control group at 48 hr. The LDH difference is significant at $p<0.05$. The tissue lactate level in the test group was three times higher than that in the control group at 24 hr and at 48 hr; the lactate/pyruvate quotient in the test group was 46 at 24 hr (controls=20) and 44 at 48 hr (controls=17). Sucrase remained unchanged throughout. Maltase was diminished in U/g protein, at 24 and 48 hr in the test group to 298 and 317, resp., compared to control group values of 434 and 358. Alkaline phosphatase in the test group rose negligibly at 24 hr and then fell significantly ($p<0.05$) after 48 hr to 875 U/g protein compared to 1,523 for the control group. Electron microscopy revealed the brush border to be intact. At 48 hr postileus, the mitochondria were generally either deformed or swollen. The hypoxia-induced absorptive changes elicited no significant structural modification, not even signs of ischemia, suggesting that the sequelae of occlusion are reversible.

7867 DISACCHARIDASES TOTAL ACTIVITY IN THE SMALL BOWEL OF RATS SUBMITTED TO EXPERIMENTAL PROTEIN DEFICIENCY. (Por.) Brasil, M. R. L.; Collares, E. F.; Soares, F. C.; Woiski, R. J. (Hospital das Clinicas, 14100 Ribeirao Preto, Sao Paulo, Brazil). *Arq. Gastroenterol.* 12(3):165-170; 1975.

7868 TOTAL AND SPECIFIC ACTIVITY OF LACTASE, INVERTASE AND MALTASE IN THE SMALL BOWEL OF MALNOURISHED RATS. (Por.) Soares, F. C.; Collares, E. F.; Brasil, M. R. L.; Woiski, J. R. (Faculdade de Medicina, Universidade de Sao Paulo, 14100 Ribeirao Preto, Brazil). *Arq. Gastroenterol.* 12(3):171-177; 1975.

7869 THE DEPRESSOR EFFECT OF DOPAMINE ON THE ELECTRICAL AND MECHANICAL ACTIVITIES OF CAT SMALL INTESTINE. (Eng.) Ohkawa, H.; Watanabe, M. (Yamaguchi Univ. Sch. Medicine, Ube, Japan). *Tohoku J. Exp. Med.* 117(1):69-77; 1975.

GENERAL

7870 EFFECTS OF ANESTHETICS ON SPLANCHNIC CIRCULATION AND METABOLISM. (Eng.) Batchelder, B. M.; Cooperman, L. H. (Univ. Pennsylvania Sch. Medicine, 3400 Spruce St., Philadelphia, PA 19104). *Surg. Clin. North Am.* 55(4):787-794; 1975.

The normal physiology of splanchnic blood flow, the measurement of hepatic blood flow (HBF), the HBF response to specific physiologic alterations, anesthetic effects on splanchnic blood flow, and the metabolic effects of altered splanchnic blood flow are discussed. In most studies of anesthetic effects on splanchnic perfusion, the HBF is estimated by measuring hepatic clearance of intravascular indocyanine green. Anesthetized patients often receive vasoactive drugs, which may alter the HBF. Alpha stimulators such as methoxamine and norepinephrine increase systemic blood pressure, but reduce HBF, as does beta blockade with propranolol. Other factors that may alter the HBF include uncontrolled hemorrhage, visceral traction during laparotomy, and hypoventilation with carbon dioxide retention. Respiration also interferes periodically with splanchnic venous outflow, and this effect is further accentuated by anesthesia. Cyclopropane and methoxyflurane reduce the splanchnic blood flow to about half that of controls, and also produce increased splanchnic vascular resistance. Halothane also decreases splanchnic blood flow, but does not change splanchnic vascular resistance. Nitrous oxide has no inherent effect on splanchnic vascular resistance or blood flow, even when combined with thiopental, muscle relaxants, and controlled ventilation at "normal" volumes. Like the general anesthetics, both spinal and lumbar epidural analgesia impair HBF. Anesthetic techniques with high ratios of splanchnic flow to oxygen consumption should be used in anesthetized patients with conditions reducing the availability of oxygen to the liver, but there is no clear evidence that any anesthetic causes harm in healthy persons.

7871 PERITONEAL EXUDATE CELLS. III. EFFECT OF GAMMA-IRRADIATION ON MOUSE PERITONEAL COLONY-FORMING CELLS. (Eng.) Lin, H.-S. (Washington Univ. Medical Sch., St. Louis, MO 63110). *Radiat. Res.* 63(3):560-566; 1975.

The effect of *in vivo* and *in vitro* gamma-irradiation on the proliferative capacity of mouse peritoneal exudate colony-forming cells (PCFC) was studied, and the dose-response curve of PCFC to irradiation was compared to that of bone marrow hemopoietic colony-forming units in culture (CFU-C). The recovery of the inducibility of PCFC by thioglycollate medium after whole-body irradiation was also investigated. PCFC was obtained and pooled 3 days after C3H/He mice received an i.p. injection of thioglycollate medium (1.5 ml). These cells were irradiated *in vitro* (0-600 rads), and a mean D_0 value of 110 rads was obtained. When irradiation was carried out *in vivo*, the D_0 value was similar (118 rads). When the dose-response curves of bone marrow hemopoietic CFU-C to gamma-irradiation (0-700 rads) *in vivo* and *in vitro* were constructed, the *in vivo* D_0 value was 124 rads, and the *in vitro* D_0 value was 135 rads. Four days after mice were whole-body irradiated with 200 rads, there was a rapid initial recovery of the inducibility by thioglycollate medium of PCFC formation; this was followed by a marked depression in the number of colony-forming cells. The levels returned to near control values at day 17. The data suggest that the sensitivity of PCFC to irradiation *in vitro* and *in vivo* is almost identical and that both PCFC and bone marrow CFU-C have a similar sensitivity to gamma-irradiation.

7872 ASSOCIATION OF SALMONELLA MUTANTS WITH GERMFREE RATS: SITE SPECIFIC MODEL TO DETECT CARCINOGENS AS MUTAGENS. (Eng.) Wheeler, L. A.; Carter, J. H.; Soderberg, F. B.; Goldman, P.

(Harvard Medical Sch., Boston, MA 02215). *Proc. Natl. Acad. Sci.* 72(11):4607-4611; 1975.

A site-specific model to detect carcinogens as mutagens is described. An association of the histidine auxotroph of *Salmonella typhimurium* (strain TA1538) within the gastrointestinal tract of otherwise germ-free Sprague-Dawley rats is maintained during periods of observation lasting as long as 7 months. The bacteria were found at levels exceeding 10^7/g in the forestomach and at levels greater than 10^8/g in the lower bowel and in the feces. Approximately 10^4 bacteria per gram were found in the posterior stomach and in the upper small intestine. The association of the salmonella mutants was maintained when the bacterial association was increased by the addition of other bacteria characteristic of the gastrointestinal flora. Carcinogenic amines, which cause strain TA1538 to revert to histidine independence in Ames' *in vitro* assays, increased the number of revertants in the feces when fed to the salmonella-associated rats. In contrast, the number of revertants in the feces did not increase when the rats were fed structurally related compounds that were not mutagenic to the bacteria *in vitro* and for which no evidence of carcinogenicity exists. Sacrifice of rats after feeding of 2-nitrofluorene indicated that the number of revertants was increased in the cecum and colon as well as in the feces. The apparent proximity of the bacterial mutagenic response to the location of the tumor response in the colon suggests that the rat associated with the histidine auxotroph may provide a useful model for further investigation of the possible association between bacterial mutagenesis and carcinogenesis within the gastrointestinal tract. In addition, with this model it may be possible to selectively evaluate the effects of various constituents of the flora on the activation of compounds provoking the revertant response.

7873 SOLUTION PROPERTIES OF SULFOBROMOPHTHALEIN SODIUM (BSP) COMPOUNDS ALONE AND IN ASSOCIATION WITH SODIUM TAUROCHOLATE (TC). (Eng.) Ware, A. J.; Carey, M. C.; Combes, B. (Univ. Texas Southwestern Medical Sch., Dallas, TX 75235). *J. Lab. Clin. Med.* 87(3):443-456; 1976.

The colloid-chemical characteristics of various BSP compounds in aqueous solution were studied, and the possibility of a direct physiochemical interaction between BSP and taurocholate (TC) was evaluated. These *in vitro* studies utilized the techniques of ultracentrifugation, freezing point depression, vapor pressure osmometry, and spectrophotometry. BSP compounds were found to self-associate in aqueous solution to form polymolecular aggregates. These aggregates were larger with unconjugated BSP, where the aggregation number apparently increased with the concentration of BSP, compared with the more polar glutathione conjugate of BSP. There was a marked physicochemical interaction between unconjugated BSP and TC and a much smaller effect between the bile salt and conjugated BSP. This interaction was minor between BSP and glycodeoxycholate or taurodehydrocholate, but was reproduced fully by glycocholate. Such an interaction between BSP and TC may have physiologic importance and may help to explain the previously noted facilitated excretion of BSP observed after infusion of TC in experimental animals.

7874 INVESTIGATIONS INTO THE METABOLISM AND MODE OF ACTION OF THE COLON CARCINOGEN 1,2-DIMETHYLHYDRAZINE. (Eng.) Fiala, E. S.; (Naylor Dana Inst. Disease Prevention, Valhalla, NY 10595). *Cancer* 36(6):2407-2412; 1975.

Chromatographic methods that allow the separation and identification of azomethane (AM), azoxymethane (AOM), and methylazoxymethanol (MAM) were applied to the analysis of bile, urine, and the exhaled air of male Fischer rats treated with ^{14}C-labeled 1,2-dimethylhydrazine (DMH) to test the hypothesis that AM, AOM, and MAM are metabolites of DMH. Investigations of the metabolism and mode of action of DMH and its derivatives by other workers are briefly reviewed. AOM and MAM were found in the pooled bile of animals injected 4 hr previously with ^{14}C-DMH and in the urine of animals injected 5-6 hr previously. AM was detected in the exhaled air of DMH-treated animals. DMH was administered to rats maintained on a semisynthetic diet containing either no additives or phenobarbital, β-naphthoflavone, or chrysene. Phenobarbital increased the multiplicity of colon adenocarcinomas, while chrysene appeared to cause a decrease in these lesions in DMH-treated rats. β-Naphthoflavone increased the multiplicity of colon adenomas over controls. The results indicate that the three microsomal enzyme inducers may have a differential effect on the reactions in the activation pathway of DMH.

7875 PERMEABILITY OF THE SMALL INTESTINE AFTER INTRA-ARTERIAL INJECTION OF HISTAMINE-TYPE MEDIATORS AND IRRADIATION. (Eng.) Kingham, J. G. C.; Loehry, C. A. (Royal Victoria Hosp., Boscombe, Bournemouth, England). *Gut* 17(7):517-526; 1976.

Permeability and selectivity of rabbit small intestine were estimated by a perfusion technique after intra-arterial injection of histamine-type mediators and intestinal irradiation. The injection of either histamine acid phosphate (0.5 mg/ml) or bradykinin triacetate (0.1 mg/ml) over a 20-min period caused a moderate increase in overall mucosal permeability concomitant with an increase in capillary permeability. The clearances of ^{125}I-polyvinylpyrrolidone (PVP), ^{3}H-inulin, ^{57}Co-vitamin B_{12}, and creatinine from plasma to intestinal lumen were increased by 290%, 190%, 120%, and 80%, resp., after the administration of histamine. The only other tracer substance used, urea, was unaffected by histamine. The clearance curves of the histamine- and bradykinin-treated loops were much flatter than the control curves, denoting a marked loss of selectivity; the slopes of the curves for histamine, bradykinin, and control were 0.021, 0.020, and 0.033, resp. Light microscopic examination of control and histamine-treated loops, stained with neutral red to show i.v.-injected carbon particles, showed an increase in capillary permeability without obvious changes in the epithelium or its basement membrane. Gamma irradiation (1,500 rads) of the intestine produced increases in the clearances of PVP

l,120%), inulin (920%), vitamin B_{12} (780%), and
reatinine (140%). Thus, the larger the molecular
eight of the tracer substance, the greater was the in-
rease in its permeation rate. The loss of selectivity
as confirmed by fractionation of the PVP; the slope
f the clearance curve of the irradiated loop was much
ess steep than that of the control curve. The authors
elieve that the loss of selectivity was partly due to
n increase in capillary permeability, but was largely
ue to damage to the epithelial basement membrane.
t is concluded that the intestinal capillary endothel-
um is both rate-limiting and selective, although not
o a major degree in either case. The epithelial base-
ent membrane, however, appears to be both rate-lim-
ting and markedly selective.

876 THE CONSEQUENCES OF ISCHAEMIA AFTER MECHANICAL OBSTRUCTION OF THE DOG ILEUM.

Eng.) Mirkovitch, V.; Robinson, J. W. L.; Menge,
.; Cobo, F. (Centre Hospitalier Universitaire Vaudois,
H-1011 Lausanne, Switzerland). *Res. Exp. Med. (Berl.)*
68(1):45-55; 1976.

xperiments were carried out in dogs to determine the
ffects of ischemia after mechanical ileal obstruction,
nd to determine whether the atrophic mucosae in the
oops below the obstruction still possessed the regen-
rative force to cope with the ischemic injury. A
echanical obstruction was produced in the ileum, and
days later, loops of intestine above and below the
cclusion were subjected to ischemia for 1 hr. This
ed to widespread morphological and functional damage
f the epithelium, indistinguishable from the response
f normal intestine. The damage consisted of de-
quamation of the epithelium and the lamina pro-
ria from the villus tips, extravasation of RBC,
isintegration of the pericryptal connective tis-
ue, complete loss of ability to absorb amino
cids or monosaccharides against a concentration grad-
ent *in vitro*, an increase in tissue water and extra-
ellular space, decreases in oxygen consumption, and
ncreases in acid phosphatase release. The recovery
f the mucosa of both loops 1 day after ischemia fol-
owed the same pattern as when no occlusion was super-
mposed. The mucosa above the obstruction had smaller
illi, shorter crypts, and smaller epithelial cells
han the contiguous untouched tissue, but the degree
f recovery was the same in normal loops, and the
oops above and below the obstruction. The transport
f phenylalanine had normalized in the ischemic loops
nd in normal tissue by the first day after ischemia,
hile that of β-methyl-glucoside remained depressed.
xygen consumption and lactate production also remain-
d depressed. The results suggest that the regenera-
ive potential of the crypts could not be obliterated
y 1-hr ischemia, either in the presence of a noxious
bstruction fluid above the occlusion or in the atro-
hic mucosa below it.

877 PATHOPHYSIOLOGY OF INTESTINAL ISCHEMIA AND ITS HEALING PROCESS.

(Eng.) Hayashi, S.;
giwara, M.; Numata, M. (Dept. Surgery I, Shinshu
niv., Matsumoto-shi, Nagano-ken, Japan). *Chir.
astroenterol.* 9(3):343-353; 1975.

The pathophysiology of intestinal ischemia and its healing process was studied in dogs with experimental ischemia, and the clinical findings in nine patients with intestinal ischemia are presented. Among the nine patients with mesenteric infarction, two were successfully treated by bowel resection. Thrombectomy or embolectomy was attempted in two other patients, but they died from massive intestinal infarction caused by occlusion of the superior mesenteric artery (SMA). In the dogs, the bowel was made ischemic by clamping the proximal SMA for 0.5-4 hr. The blood 5-hydroxytryptamine (5-HT) levels were increased during ischemia. In dogs that experienced bowel ischemia for up to 3 hr, the 5-HT levels returned to control levels after the clamp was removed; these dogs also recovered from shock. Dogs that experienced ischemia for 4 hr remained in shock, and the 5-HT levels remained high until death. Dogs that were ischemic for 30-45 min survived until the time of sacrifice, which was up to 20 days following the induction of ischemia. Five of 15 dogs that underwent ischemia for 50 min died within 3 days after the clamp was released, and four of the remaining animals had diarrhea. Twelve of 14 dogs that were ischemic for 60-90 min died within 4 days. The most significant pathological changes in the middle portion of the small intestine were found in the dogs that underwent ischemia for 50 min or more. Shallow ulceration, epithelial degeneration, and vasodilatation were observed 4 days after the dogs underwent 50-min ischemia. In dogs ischemic for 30-45 min, the hexosamine concentrations increased in both the mucosa and muscle layer 4-6 days after the restoration of mesenteric flow. The hydroxyproline concentration was also increased at 10 days after the restoration of mesenteric flow. Three dogs in which experimental SMA stenosis to one-fourth of the original caliber had been produced died from massive bowel necrosis within 3 days of the operation; three of nine dogs with stenosis of one-third the original caliber died within 10 days. However all of 16 dogs with stenosis of one-half the original caliber survived the operation. Although clinical cases may tolerate longer periods of intestinal ischemia, early diagnosis, immediate laparotomy with an adequate therapeutic technique (i.e., meticulous vascular surgery and bowel resection), and various supportive therapy are necessary.

7878 ACUTE ISCHEMIC CHANGES IN INTESTINAL MUSCULARIS.

(Eng.) Ming, S.-C.; McNiff, J. (Dept. Pathology, Temple Univ. Medical Sch., 3400 Broad St., Philadelphia, PA 19140). *Am. J. Pathol.* 82(2):315-326; 1976.

The morphologic alterations in the mouse intestinal muscularis occurring within 24 hr of ischemia were investigated. Ischemia of the small bowel was produced in 12 mice, and 15-120 min after onset, the intestinal wall at the midpoint of the ischemic segment was excised. Since the mice did not survive beyond 2 hr, ischemic effects from 2-24 hr were studied *in vitro*. The ischemic muscle cells in both circular and longitudinal layers showed progressively severe alterations with time. Ultrastructural changes were evident at 15 min. Within 1 hr, three prominent changes occurred: contraction of cells, unevenness of the sarcoplasmic density, and markedly increased dense patches with focal enlargement of cell diameter. After 2 hr, the cells were irregular in both size and shape. An increasing degeneration and lysis of myofilaments resulted in dense degenerative bands and nodules alternating with clear segments. By 4 hr, the myofilaments disintegrated. The mitochondria were condensed, shrunken, and fragmented. By 8 and 24 hr, there was total destruction of the cells, with only irregular patches of amorphous granular material remaining. The plasma membrane had largely dissolved and the intercellular space could no longer be recognized. Nuclei had disappeared from many cells. The profound derangement of myofilaments offers a morphological basis for the decrease of electrical slow waves and loss of tone in the ischemic bowel muscle of experimental animals and man.

7879 DIGESTIBILITY OF PROTEIN AND DRY MATTER IN CAECECTOMISED AND INTACT RATS.

(Eng.) Dreyer, J. J.; Concannon, T. R. J.; De Klerk, W. A. (National Food Res. Inst., CSIR, Pretoria, South Africa). *S. Afr. Med. J.* 49(40):1661-1666; 1975.

To determine the effect of the microbial activity in the cecum on total dry matter digestibility (DMD) and on protein digestibility, cecectomized and intact rats were studied. The DMD of uncooked maize and the digestibility of the protein in cooked methionine-supplemented yellow haricot beans were determined. Cecectomized and intact rats received a diet containing 0, 250, 500, 750, or 1,000 g of maize meal or a diet containing 179, 448, 717, 985, or 1,254 g of methionine-fortified yellow haricot beans (1.20, 1.68, 2.16, 2.63, or 3.16% N, resp.). The mean maize DMD levels in intact and cecectomized rats were 99% and 90%, resp. The methionine-supplemented bean protein was 77.7% digestible in intact rats and 79.9% digestible in cecectomized animals. These results suggest that microbial activity causing gas formation in the cecum results in an appreciable loss of dry matter, but that the presence of the cecum does not affect protein digestibility.

7880 THE INFLUENCE OF A CHEMICAL DIET ON THE INTESTINAL MUCOSA AFTER JEJUNO-ILEAL BYPASS IN THE RAT.

(Eng.) Fenyo, G.; Hallberg, D. (Surgical Res. Lab., Karolinska sjukhuset, Stockholm, Sweden). *Acta Chir. Scand.* 142(3):270-274; 1976.

The role of diet in stimulating compensatory hypertrophic changes in the intestine was investigated in rats after jejuno-ileal bypass surgery to exclude about 85% of the small intestine. One group of rats was fed pellet food *ad libidum,* and the other was fed 27 g of a chemically well-defined diet (Vivasorb) daily, to give the least possible intraluminal stimulus with full nourishment. Control sham-operated animals were also maintained in each of the two diets. Intestinal biopsy was carried out after 2 weeks, at which time the sham-operated pellet group had gained 7% in body weight, the shunt-operated pellet group had lost 8.9%, the sham-operated Vivasorb group had gained 4.6%, and the shunt-operated Vivasorb group had lost 27%. The functioning part of the jejunum and ileum in both shunted groups became hypertrophic, while the bypasse portion became atrophic and narrow. Water evaporatio was measured in 3-cm segments taken from various portions of the intestine. Shunt-operated animals had a significantly higher percentage of water evaporation than controls, regardless of diet ($p < 0.05$ for pellets and $p < 0.001$ for Vivasorb). Wet and dry weights of i testinal segments from pellet-fed shunted animals wer significantly higher than those from sham-operated an mals. In the Vivasorb animals, similar increases in dry and wet weights were observed, except in the bli loop of shunted animals where significant atrophy was noted. Among sham-operated animals, the Vivasorb gro had a significantly lower intestinal weight, except f the most proximal segment. Among shunted animals, th pellet group had a higher weight increase (wet and dry) than the Vivasorb group. In shunted pellet-fed animals, villus height was significantly increased, except in the blind loop. In shunted Vivasorb-fed an imals, villus height was significantly increased, except in the blind loop where significant atrophy was observed. In shunt-operated animals, the pellet diet was superior to Vivabsorb for inducing an increase in villus height. It is concluded that a chemically defined, virtually bulk-free diet is capable of stimula ting the mucosa of the small intestine to develop compensatory adaptive changes.

7881 ADRENERGIC INFLUENCES ON THE ELECTRICAL POTENTIAL ACROSS THE COLONIC MUCOSA OF THE RABBIT.

(Eng.) Lennane, R. J.; Peart, W. S.; Shaw, J. (St. Mary's Hosp. Med. Sch., Univ. London, London, W21PG, England). *J. Physiol.* 250(2):367-372; 1975.

The role of adrenergic changes in the transient increase in potential difference (PD) seen in the colonic mucosa of rabbits subjected to handling and restraint was studied. In 20 normal rabbits, the mean colonic PD, which was 9.45 mV before the experiment, rose to 27.04 mV 2 hr after the animals were wrapped in a drape and restrained. Four hours after the animals were unwrapped and returned to their cages, the PD had returned to 11.3 mV. Adrenalectomy did not significantly alter the response to handling. Adrenergic block was produced by the administration of pentolinium (50 mg, i.v.) to normal or adrenalectomized rabbits or the administration of guanethidine (12.5 mg/kg 1 day for 3-5 days, i.v.) to adrenalectomized rabbits. Adrenergic block abolished the response to handling; the initial mean PD of 13.3 mV fell in all six animals tested to 9.67 mV 2 hr after handling. After α-adrenergic block by the i.v. infusion of phenoxybenzamine (6 mg/kg, over 20-30 min), the initial mean colonic PD of 17.5 mV rose to 28.4 mV following handling. In animals that received propranolol (0.4 mg/kg/10 min, i.v.) to achieve β-adrenergic block, the initial PD of 11.4

mV decreased to 8.70 mV after handling. In animals that received neosynephrine (0.6 μg/kg/min, 2 hr), an α-adrenergic agonist, the initial colonic PD of 5.50 mV increased to 11.8 mV. β-Adrenergic stimulation with isoproterenol sulphate (0.1 μg/kg/min, 2 hr) resulted in an increase in PD from an initial value of 7.36 mV to 43.1 mV after handling. The administration of atropine sulphate (3 mg followed by 0.1 mg/kg/min continuous infusion) did not change the response to handling seen in untreated animals. The results indicate that the change in colonic PD with handling is a direct effect of the autonomic nervous system mediated via β-receptors and that the changes are not related to the effects of circulating catecholamines or to changes in aldosterone production.

7882 HEPATITIS TRANSMISSION IN MARMOSETS.

(Eng.) Appleton, H. (Central Public Health Lab., Colindale Ave., London NW9 5HT, England). *J. Infect. Dis.* 132(5):500-505; 1975.

The suitability of marmosets for hepatitis studies was assessed. Because the relationship of two sera (Barker and Berlin strains) to human hepatitis is uncertain, an attempt was made to establish a new strain by the direct inoculation of sera from patients with infectious hepatitis. Abnormal transaminase activity occurred in 75% of 44 animals originally inoculated with the Barker agent, but when histological and biochemical results were considered together, a positive diagnosis of hepatitis was made in only 41%. No difficulty was experienced in the transmission of the Berlin agent to marmosets; five of six animals developed hepatitis following inoculation. Normal human immunoglobulin failed to protect against infection with the Berlin agent. Animals that had been successfully infected with the Barker agent failed to develop hepatitis on subsequent challenge with the Berlin agent. Animals that had been resistant to infection with the Barker agent also resisted infection when later challenged with the Berlin agent. Four hepatitis B surface antigen-free serum pools were prepared from patients with acute infectious hepatitis. Although some animals injected with one of the first three pools developed raised SGOT levels, attempts to passage the agent were unsuccessful. Hepatitis B surface antigen-positive serum, obtained from a patient with chronic hepatitis, also did not induce hepatitis in marmosets, and neither antigen nor antibody was detected in these animals. The authors conclude that more reliable and consistent results would be obtained from marmosets from a successful breeding colony, rather than from wild marmosets.

7883 HISTOLOGICAL AND CYTOLOGICAL STUDIES ON HEPATOCARCINOGENESIS IN RATS BY ADMINISTRATION OF DIETHYLNITROSAMINE.

(Eng.) Takayama, S.; Hitachi, M.; Yamada, K. (Dept. Experimental Pathology, Kami-Ikebukuro 1-37-1, Toshima-ku, Tokyo 170, Japan). *Gann Monogr. Cancer Res.* 17:343-354; 1975.

The histological and cytological changes associated with diethylnitrosamine-induced hepatocarcinogenesis were studied in male Donryu rats. The rats received 50 ppm of diethylnitrosamine (DEN) in the drinking water for 2, 3, or 4 weeks. The first liver tumor was found in a rat sacrificed during the 34th week that had been fed DEN for 2 weeks. In the group fed DEN for 2 weeks, liver tumors were found in 3 of 24 rats killed up to 78 weeks. In the animals fed for 3 weeks, liver tumors were found in 14 of 32 rats killed up to 59 weeks, and in the animals fed for 4 weeks, tumors were found in 9 of 20 rats killed up to 44 weeks. In animals that received 50 ppm DEN for 3 weeks, areas of hyperplasia were observed in the liver immediately after the end of DEN administration. Nodular hyperplasia was seen after 14 weeks, and liver tumors occurred after about 30 weeks. Four weeks after DEN administration was discontinued, the incidence of near-triploid and tetraploid cells was 22.2%, and 8 weeks after discontinuation, the incidence was 20.5%. By 20 weeks, the incidence of abnormal chromosomes had decreased to 8.8%. A large number of the dividing cells in the DEN-induced liver cell carcinomas were chromosomally abnormal diploid cells. The authors conclude that the observed cytogenetic changes are relevant to the subsequent development of tumors.

7884 AN ANTIGEN COMMON TO PRENEOPLASTIC HEPATOCYTE POPULATIONS AND TO LIVER CANCER INDUCED BY N-2-FLUORENYL-ACETAMIDE, ETHIONINE, OR OTHER HEPATOCARCINOGENS.

(Eng.) Okita, K.; Farber, E. (Fels Res. Inst., Temple Univ., Philadelphia, PA 19140). *Gann Monogr. Cancer Res.* 17:283-292; 1975.

Current knowledge of precursor populations for hepatocellular carcinoma is reviewed, and new data indicating the presence of a highly reproducible positive marker for preneoplastic liver cells are presented. In addition, new data concerning the basis for nodular proliferation and a possible role of arrested differentiation in this phase of carcinogenesis are reported. A new common antigen, preneoplastic (PN) antigen, has been found in rats in both early and late hyperplastic nodules induced by N-2-fluorenylacetamide (2-FAA) or ethionine and in primary hepatocellular carcinomas induced by 2-FAA, ethionine, 3'-methyl-4-dimethylaminoazobenzene, dimethylnitrosamine, or diethylnitrosamine. In the present study, experiments concerning the subcellular distribution of PN antigen in hyperplastic nodule tissue revealed that the antigen is probably microsomal. Antiserum to the crude antigenic preparations induced in rabbits was absorbed with a crude preparation from normal rat liver. The supernatants were tested after absorption for antibody against hyperplastic liver nodules. A highly reproducible antibody to one or more components in the hyperplastic nodule was found in all antisera prepared against nodule tissue. An apparently identical precipitation line was found when antigen preparations from hyperplastic nodules or from primary hepatomas were used. Thus, the presumed preneoplastic and the neoplastic cell populations contain some antigenic component(s) not present in normal liver. The antigen was not found in normal mature rat liver, fetal liver, amniotic fluid, adult normal serum, serum from rats with hyperplastic nodules or primary hepatomas, or in normal kidney, spleen, heart, lung, gastrointestinal tract, or brain. Immunofluorescent staining showed that it was present only in hepatocytes in hyperplastic nodules or in primary hepatomas. The PN antigen did not seem to be related to rat group-specific (gs) 1-antigen or gs 3-antigen. The PN antigen may be related to an interruption in differentiation or remodeling of liver parenchyma. The possible use of such an antigen in the study of human cirrhosis and cancer, and in carcinogenesis in other organs is discussed.

7885 EFFECTS OF α-AMANITINE ON CHROMATIN IN REGENERATING RAT HEPATOCYTES: A BIOCHEMICAL AND MORPHOLOGICAL STUDY.

(Eng.) Derenzini, M.; Marinozzi, V.; Novello, F. (Istituto de Patologia Generale dell'Universita di Bologna, Via S. Giacomo 14, 1-40126 Bologna, Italy). *Virchows Arch. [Zellpathol.]* 20(4):307-318; 1976.

In an attempt to correlate the morphologic pattern of chromatin with its activity in nucleic acid synthesis, the ultrastructure and the changes in RNA and DNA synthesis were studied in the regenerating hepatocytes of partially hepatectomized Wistar rats treated with α-amanitine. At 15 hr after hepatectomy, RNA synthesis increased above 75%; synthesis continued to be elevated at 24 hr, although the increase was reduced to 42%. Thirty minutes after the i.p. injection of α-amanitine (50 µg/100 g), a 52% inhibition of RNA synthesis occurred. A 10-fold increase in DNA synthesis occurred at 24 hr after hepatectomy. α-Amanitine had no effect on DNA synthesis until 4 hr after administration, when the rate of thymidine incorporation was reduced from a mean level of 32.49 disintegrations per min (dpm) per g DNA to 15.79 dpm/g DNA. Almost all the chromatin in the nuclei of regenerating hepatocytes appeared as decondensed chromatin 15 hr, and particularly 24 hr, after partial hepatectomy. α-Amanitine induced a clear condensation of chromatin as early as 30 min after administration. The degree of condensation increased progressively until 2 hr after administration, when almost all chromatin was condensed. Because DNA synthesis was unchanged during the first 2 hr after α-amanitine administration, it is concluded that chromatin condensation did not affect the DNA synthesis.

7886 THE DEVELOPMENT OF THE GUINEA PIG GALLBLADDER EPITHELIAL CELLS.

(Ger.) Schiebler, T. H.; Lang, K.; Wahlin, T. (Anatomisches Institut der Universitat Wurzburg, D-8700 Wurzburg, Koellikerstr. 6, W. Germany). *Histochemistry* 45(3):177-190; 1975.

The localization of mucosubstances in the developing guinea pig gallbladder epithelium was studied histochemically by light microscopy. The gallbladders of 106 guinea pigs were examined, including 60 embryos, 22 animals on postnatal days 1-31, and 24 adults. All of the developmental decisive steps in the gallbladder epithelium occur between embryonic day 30 and postnatal day 10. Prior to embryonic day 30, the gallbladder epithelium lacks any morphological or histochemical characteristics. The developmental midpoint is embryonic day 45-63; the gallbladder is essentially adult by postnatal day 10. Between embryonic day 30-44, the nuclei assume a deeper position and the pseudostratified columnar epithelium changes to simple columnar epithelium with numerous mitoses. Nuclear division takes place almost exclusively in the apical regions. Basal membranes are deficient, and cell migration on the superficial epithelium is visible. In this interval, there is invagination of the underlying mesenchyme. Gradually increasing levels of neutral and carboxylated mucoproteins in apical and subapical gallbladder epithelium are also demonstrable by embryonic day 30-44; they are PAS-positive and amylase resistant. During embryonic day 30-57, rich glycogen deposits develop; their onset is early, increasing especially between embryonic day 45 and 55, and then disappearing completely. Their location is mainly basal and subapical. On embryonic day 48, strongly acidic sulfated glycoproteins appear in the invaginations, increasing steadily to adult levels by embryonic day 63. The supranuclear cytoplasm appears to be decisive in the sulfation process. "Light cells" appear on embryonic day 58, are reduced in number postnatally, and remain deep in the smaller invaginations after postnatal day 6 and in the adult guinea pig. They form small clusters between the epithelial cells and certain carboxylated and neutral, but little-sulfated, mucosubstances. There are no goblet cells, but transient glandular cells are not uncommon. Only some prenatal epithelial cells are secretory, but this changes postnatally, as the increasing volume and pigmentation of the gallbladder contents indicates; the acid mucosubstances are evidently involved. The apical and subapical mucus of adult epithelium is heavily sulfated, resistant to neuraminidase, hyaluronidase, and amylase, and contains carboxyl groups. According to conventional classification, GC-mucin A and S-mucin A are involved.

7887 EXPERIMENTAL SURGERY IN PANCREAS AUTOTRANSPLANTATION.

(Ger.) Meyer, W.; Kivelitz, H.; Petersen H.; Steinmeyer, Ch. (Chirurgische Univ.-Klinik, D-4000 Dusseldorf, Moorenstr. 5, W. Germany). *Langenbecks Arch. Chir.* 340(2):107-115; 1975.

Pancreatic autotransplantation was performed in dogs to study exocrine and endocrine behavior after denervation and interruption of lymph drainage and to clarify the onset of fibrosis in cases of a nonligated pancreatic duct. Laparotomies and one-stage heterotopic pancreaticoduodenal autotransplantations, including cholecystojejunostomy, gastrojejunostomy, and duodenojejunal anastomosis, were performed in 10 dogs. Six animals died of technical error and two died of hemorrhagic pancreatitis. The remaining two survived 7 and 12 months. Initial weight loss and increased fecal fat was attributed to depressed exocrine function. Immediate postoperative values included a 66.7% hematocrit, 21,900 leukocytosis, serum amylase elevation (2,120 Somogyi units), and transient hyperglycemia (114 mg%). Several months postoperatively, the amylase and blood sugar were normalized. Tolbuamide assay on days 8-75 found an insulin surge, fter which the hypoglycemic interval was longer han that of control animals. Glucose tolerance on ostoperative days 59 and 132 showed a brief increase, hen a decrease and normalization within 2 hr. No iarrhea or steatorrhea occurred in the dogs, but low-grade increase in fecal fat continued. Macroscopic review of the transplant 4 months postoper- tively found no edema or anastomotic fistulas. istologically, normal acinar cells were present ithout fibrosis and the islets of Langerhans were nchanged. This experimenatal model is useful for he long-term evaluation of heterotopic transplanta- ion of the pancreas. Denervation and lymphatic in- erruption may cause a transient but not definitive nfluence on pancreatic endocrine and exocrine unction.

888 CORRELATION OF ^{85}Kr GASTRIC MUCOSAL FLOW DETERMINATIONS. (Eng.) Jochimsen, P. R.; osin, H. (Dept. Surgery, Univ. Iowa Hosp., Iowa ity, IA 52242). *J. Surg. Res.* 19(5):309-313; 1975.

he use of ^{85}Kr in the determination of mucosal flow s described, and the accuracy of this method was ompared with that of ^{86}Rb clearance. The two me- hods are based upon widely different assumptions: he ^{85}Kr method is based upon the monoexponential ecay of a flow-limited substance, and the ^{86}Rb ethod is based upon fractional clearance or uptake. aseous ^{85}Kr dissolved in saline, at a specific ac- ivity of 0.8 mCi/cm^3, was injected as a 0.1-cm^3 olus into the splenic arteries of 16 dogs. Three ^{5}Kr determinations were made, followed by an i.v. njection of ^{86}Rb. The mean of three mucosal blood low determinations by the ^{85}Kr method was compared ith a single determination by the ^{86}Rb method. The ean ratio of ^{86}Rb-determined flow to ^{85}Kr-deter- ined flow was 0.99 ± 0.12. A plot of the ^{86}Rb- etermined mucosal flow versus the ^{85}Kr-determined low revealed a correlation coefficient of +0.893, ndicating a close agreement between the two methods. he results suggest that both methods measure muco- al blood flow accurately.

7889 THE EFFECT OF NEUROLEPTICS ON THE DEVELOPMENT OF GASTRIC ULCERS IN RATS EXPOSED TO RESTRAINT-COLD STRESS. (Eng.) Hano, J.; Bugajski, J.; Danek, L.; Wantuch, C. (Inst. Phar- acology, Polish Acad. Sciences, 52, Ojcowska, 31-344 Krakow, Poland). *Pol. J. Pharmacol. Pharm.* 28(1):37-47; 1976.

xperiments were carried out in Wistar rats to de- ermine how and to what degree severe neurogenic tress induces the occurrence of biochemical and orphological changes in rats, to what degree neu- oleptics prevent changes provoked by the action of cute stress, and whether changes in the secretory unction of the gastric mucosa in stress conditions ight elucidate the development of hemorrhagic les- ons in the stomach. When rats were subjected to hilling and immobilization, the incidence of gas- ric lesions increased with time, reaching 85% at hr. The blood glucose concentration rose slight- y during the first hour of stress, after which it fell by 30-57% in the third and fourth hours. The serum free fatty acid level increased by 80% in the third hour of stress. Immobilization alone at 18 C caused a significant decrease, 27-42%, in the volume of gastric secretion. When the temperature was lowered to 6 C, the volume of the secretion decreased by as much as 61%. The i.p. administration of chlorpromazine, thioridazine, or spiroperidol (1, 5, or 10 mg/kg) 0.5 hr before stress produced hyperglycemia in rats not subjected to stress; within 3 hr after the injection of the higher doses, the rise in glucose concentration reached 28%. In stressed rats, chlorpromazine, thioridazine, and spiroperidol caused hyperglycemia, and the higher doses increased the glucose level by 49-104%, while fluphenazine (0.01 mg/kg) had no effect. All doses of chloropromazine attenuated the development of hemorrhagic lesions of the gastric mucosa; the two larger doses decreased the number of animals in which gastric ulcers developed during stress. The index of the preventive action after the highest dose of chloropromazine was 80%, and after the 1- and 5-mg/kg doses was 67% and 58%, resp. Thioridazine also diminished the incidence of ulceration in stressed animals by 41-77%. Stress ulceration was diminished by 77-90% in animals treated with spiroperidol. The administration of fluphenazine at 0.01 and 0.1 mg/kg reduced the number of hemorrhagic lesions and the ulcer index by 65%; 1-10 mg/kg of fluphenazine increased both the incidence and the ulcer index in stressed rats. Chlorpromazine and thioridazine decreased the serum K level by 6-26% in stressed rats. The prevention of gastric ulceration by neuroleptics might be the result of their antisecretory action and the inability to counteract the breakdown of sympathetic activity during severe stress.

7890 SEPARATION OF GASTRIC MUCOSAL CELLS OF RAT WITH PROTEOLYTIC ENZYMES, PRONASE AND TRYPSIN, WITH SPECIAL REFERENCE TO THE COLLECTION, MORPHOLOGY AND VIABILITY OF THE GENERATIVE CELLS. (Eng.) Kurokawa, Y.; Saito, S.; Kanamaru, R.; Sato, T; Sato, H. (Res. Inst. Tuberculosis, Leprosy, Cancer, Tohoku Univ., Sendai, Japan). *Tohoku J. Exp. Med.* 116(3):241-252; 1975.

Methods to obtain cell suspensions from the neck zone of the gastric mucosa of rats with high ratios of G cells are reported and evaluated. Better results were achieved with pronase (1.0%) than with trypsin (2.0%) in collecting single isolated cells, with higher cell yields and viability. The cells dissociated with trypsin retained glandular structures as *in situ*. The measurement of radioactivity revealed that the incorporation of ^{3}H-thymidine into generative cells was highest in the cell suspension collected by the second 15-min dissociation. It is concluded that the most effective method of obtaining dissociated cells from the generative zone of the mucosa is to collect the cells dissociated with 1.0% pronase continuously for a period from 15 to 45 min after the start of dissociation. On autoradiographic analysis with ^{3}H-thymidine, the ratio of generative cells was 10%, approximately 3 x 10^{6} cells, in the specimens.

7891 FUNCTIONAL CHARACTERISTICS OF PEYER'S PATCH CELLS. III. CARRIER PRIMING OF T CELLS BY ANTIGEN FEEDING. (Eng.) Kagnoff, M. F. (Dept. Medicine, Univ. California, San Diego, La Jolla, CA 92037). *J. Exp. Med.* 142(6):1425-1435; 1975.

The possibility that the p.o. administration of antigen (chicken or sheep RBC) leads to a priming of thymus-derived (T) cells in Peyer's patches was studied in BDF_1 mice. Carrier priming was assessed by measuring the ability of irradiated Peyer's patch cells from sheep RBC-fed mice to enhance the anti-trinitrophenyl (TNP) response of Peyer's patch cultures stimulated with TNP-sheep RBC. The addition of irradiated Peyer's patch cells from sheep RBC-fed mice to normal Peyer's patch cultures consistently enhanced the specific anti-TNP and anti-sheep RBC response of normal Peyer's patch culture four- to fivefold. Priming of T helper cells occurred when the RBC were administered p.o., but not when they were injected i.v. or i.p. When the experiment carried out in control mice or mice fed chicken RBC, the anti-TNP response was not enhanced. Antigen feeding did not result in significant induction of Peyer's patch B cells to humoral antibody synthesis *in vivo*. Since Peyer's patch T cells can be carrier-antigen primed for helper function in the absence of B-cell induction to humoral antibody synthesis, these studies may indicate that T-cell priming is less dependent than B-cell induction on cooperating accessory adherent cells.

DIAGNOSTIC PROCEDURES

7916 IMMUNOELECTROPHORESIS TEST IN AMOEBIASIS. (Eng.) Vinayak, V. K.; Tandon, B. N.; Talwar, G. P.; Mohapatra, L. N.; Prakash, O. (Postgraduate Inst. Medical Education Res., Chandigarh, 160011, India). *Indian J. Med. Res.* 64(5):661-667; 1976.

The value of the immunoelectrophoresis (IEP) test in the diagnosis of amebiasis was compared with that of the agar gel diffusion (GEL) and the indirect hemagglutination (IHA) tests, using a common amebic antigen. Amebiasis was detected by the IEP test in 41 of the 45 patients (91.1%) with invasive amebiasis. Gel detected 38 cases (84.4%), and the IHA test detected 42 cases (93.3%). No false-positive reactions were obtained with the IEP and GEL tests, whereas the IHA test gave positive reactions in 14.2% of 35 patients with nonamebic intestinal and hepatic disorders and in 10.0% of 30 healthy subjects. Several bands were obtained in immunoelectrophoretic slides, but one prominent band located near the well was considered to be characteristic for amebiasis. A comparison of the three tests revealed that, although the IHA test is slightly more sensitive, the IEP test is more discriminatory and coincided better with clinical investigations.

7917 RADIOLOGICAL CHANGES IN AMOEBIC LIVER ABSCESS. (Eng.) Naik, G. A.; Kamat, G. R.; Vibhute, J. V. (Jaslok Hosp. Res. Center, Bombay 40016, India). *Indian J. Radiol.* 29(2):89-95; 1975.

The radiologic changes seen in 73 patients with amebic liver abscesses are presented. A significant elevation of the right dome of the diaphragm was seen in 62% of the cases when the conventional posteroanterior view was used; this was increased to 73% when a right lateral view was used. A localized bulge in the diaphragm was seen in 53% of cases, and flattening occurred in 23%. The two most common pleuropulmonary abnormalities were occlusion of the right costophrenic angle (40%) and right oblique fissure thickening (58%). Obscuring of the hepatic angle, downward enlargement of the liver, and downward displacement of the hepatic flexure occurred in 15%, 67%, and 68% of the cases, resp. The right kidney was displaced downward in 12%. If the conventional posteroanterior radiographic view of the chest does not reveal any abnormalities in a patient with suspected amebic liver abscess, it is essential to also use a right lateral view and to perform a plain abdominal radiograph.

7918 PROBLEMS IN DISTINGUISHING TUBERCULOSIS OF BOWEL FROM CROHN'S DISEASE IN ASIANS. (Eng.) Burke, G. J.; Zafar, S. A. (Bulawayo Group Hosps., Bulawayo, Rhodesia). *Br. Med. J.* 4(5993): 395-397; 1975.

The cases of five Asian patients with intestinal tuberculosis who were initially thought to have Crohn's disease are presented. The first patient, a 23-yr-old Pakastani man, was hospitalized four times before the correct diagnosis was made. His symptoms included abdominal pain, vomiting, diarrhea, constipation, and weight loss. Two initial diagnoses were perforated duodenal ulceration and diverticulitis. At the third admission, a barium enema examination revealed three internal fistulae arising from the rectum, rectosigmoid, and distal sigmoid colon, and the terminal ileum was seen to have a narrowed lumen with proximal stasis and dilatation. Crohn's disease was diagnosed, but a subsequent chest x-ray disclosed a left apical focus, and cultures of feces, urine, and sputum grew *Mycobacterium tuberculosis*. The patient responded to chemotherapy. The second patient, a 10-yr-old Indian boy, had intermittent right-sided pain following an ileotransverse colostomy for a large cecal mass. A chest x-ray revealed a primary, calcified complex. *M. tuberculosis* was cultured from an abscess that discharged spontaneously on the anterior abdominal wall. The third patient, a 54-yr-old Pakastani woman, presented with acute intestinal obstruction. Laparotomy revealed ileocecal obstruction secondary to a mass in this region, with an ulcer crater and a few tubercle-like lesions of the serosal surface of the ileum. The chest x-ray was initially normal. A side-to-side ileotransverse anastomosis and right hemicolectomy were performed. A subsequent chest x-ray revealed active tuberculosis. At the site of the anastomosis, the segment was narrowed, the mucosa was destroyed, and deep "rose thorn" ulcers were present. Barium enema in the fourth patient, a 31-yr-old Pakastani man, revealed a narrowing of part of the transverse colon, with a cobblestone appearance and irregular contours. The ascending colon was narrowed, with a loss of haustration and "collar-button" ulcers. There was a fistula between the ileum and ascending colon. The fifth patient, a 35-yr-old Indian woman, had a palpable mass in the right iliac fossa, and a barium meal disclosed dilated loops in the terminal ileum. At surgery, granulomatous giant cell inflammation was seen in the muscularis mucosa. Tuberculous bowel disease should be considered in immigrant patients presenting with abdominal symptoms and a mass.

7919 THE ROLE OF COLOSCOPY IN THE DIFFERENTIAL DIAGNOSIS BETWEEN IDIOPATHIC ULCERATIVE COLITIS AND CROHN'S DISEASE OF THE COLON. (Eng.) Banche, M.; Rossini, F. P.; Ferrari, A.; Roatta, L.; Gilli, E.; Cirillo, R. (Facolta di Medicina e Chirurgia dell'Universita di Torino, Torino, Italy). *Am. J. Gastroenterol.* 65(6):539-545; 1976.

Experience with coloscopy in the diagnosis of Crohn's disease and idiopathic ulcerative colitis (IUC) is presented. Between 1971 and 1974, 2,478 coloscopies were carried out; 182 cases of IUC and 104 cases of Crohn's disease were diagnosed. The annual incidence of IUC was about the same over the 4-yr period, whereas that of Crohn's disease increased. The percentage of patients with Crohn's disease increased from 0% in 1971 to 45.38% in 1974. Endoscopic features of IUC include: diffuse edema and shiny mucosa, bleeding on contact, widespread ulcerations, oozing hemorrhages, friable inflammatory polyps, granularity of mucosal surface, noninfiltrated walls and absence of haustra, little or no motility, and abundant secretion. Endoscopic features of Crohn's disease include: well-de-

ned areas of hyperemia, no bleeding on contact,
hta-like ulcerations, normal mucosa surrounding
sions, flat lengthwise ulcers with red edges, no
zing hemorrhage, hard papular formations, cobble-
one mucosa, wall rigidity, little or no secretion,
stula orifices, and stenosis. Coloscopy was useful
distinguishing different stages of both IUC and
ohn's disease, and may be regarded a useful proce-
re in diagnosing nonspecific inflammatory diseases of
e colon.

20 FOCAL AND GENERALIZED HEPATIC LESIONS: A COMPARISON OF LIVER SCANS WITH ANATOMIC
D HISTOLOGIC FINDINGS.

(Eng.) Ferlin, G. (Osped-
e Generale Provinciale, Castelfranco Veneto, Italy).
Nucl. Biol. Med. 19(3):135-144; 1975.

28 normal patients and 150 patients with liver
seases, the results of scintiphotography were
mpared with histologic and anatomic findings
tained with biopsy (111 cases), percutaneous
edle biopsy (15 cases), and surgery or autopsy
2 cases). Liver images were obtained using
^{m}Tc-sulfur colloid and scanner or Anger camera.
o groups of images, one characterized by cold
eas only (51 cases), and the other by generalized
normalities and variable degrees of spleen and
ne marrow uptake (74 cases), agreed with anatomic
d histologic findings in 45 (90%) and 71 (96%)
ses, resp. Twenty-two liver studies, showing
neralized abnormalities with intense extrahepatic
ticuloendothelial system uptake and focal lesions
re included in a third group: in nine of these
ses (46%), there was cirrhosis and cancer. In
patients, the images were normal; 21 had no
ver disease (67%), 3 had metastatic lesions, and
had fatty liver. Scintiphotography was abnormal
93% of liver diseases (140 cases). In 146 cases
2%), there was complete agreement with anatomical
d histological findings.

21 ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY.

(Ger.) Soehendra, N.; Rehner, M.; Zimmer,
; Wehling, H. (Chirurgische Universitatsklinik, 2
mburg 20, Martinistrasse 52, W. Germany). *Med.
in.* 70(21):935-940; 1975.

e role of endoscopic retrograde cholangiography (ERC)
biliary disease is detailed. The study comprised
1 ERC procedures, representing a success rate of
% from an initial 134 probes. Target or selective
le duct presentation was achieved in 83 of 100
ials. The range of ERC findings included 16 cases
th no pathology, 12 with cholecystolithiasis, 10
th choledocholithiasis with or without papillary
enosis, 6 with intrahepatic cholestasis, 9 with
stcholecystectomy papillary stenosis, 5 with
olecystolithiasis and choledocholithiasis, 5 with
olecystolithiasis and papillary stenosis, 5 with
choledochoduodenostomy, 3 with cystic stump
ndromes, 3 with carcinoma of the common duct, 3
th carcinoma of the head of the pancreas, and
her disorders including 1 case each of gall-
adder carcinoma, liver metastases, and 1 papil-
ry adenoma. Among these were 26 cholecystectomies,
5 choledoduodenostomies, 2 Billroth I operations, 2 Billroth II operations, and 1 partial duodenopancreatectomy. Acute pancreatitis is the most frequent severe side-effect (2% of the cases); acute cholecystitis has also occurred; both side-effects arise from filling defects. To avoid air-pocket simulation of stones, the cannula must be carefully filled with contrast medium. False images of ductal occlusion can result from incomplete filling, which is tractable by proper pressure control. Contraindications include acute pancreatitis or pancreatic cysts, severe decompensated corpulmonale, and aortic aneurysm. Special indications include suspected cholestases, unclear persistent or recurring complaints after biliary surgery, and liver tumors.

7922 ANTEGRADE VISUALIZATION OF BILE DUCTS BY PERCUTANEOUS TRANSJUGULAR CHOLANGIOGRAPHY.

(Ger.) Huchzermeyer, H.; Luska, G.; Freyschmidt, J. (Abteilung Gastroenterologie, Dept. Innere Medizin, Medizinische Hochschule Hannover, Hannover, W. Germany). *Leber Magen Darm* 6(1):8-14; 1976.

Experiences with antegrade presentation of the bile ducts in 22 patients are reported and compared with other cholangiographic methods. The accuracy of percutaneous transjugular cholangiography (PTC) is 88-93%, which is higher than that for transhepatic cholangiography. The PTC was unsuccessful in three patients who showed only a slight elevation in cholestasis enzymes and a bilirubin level below 2 mg%. Higher bilirubin levels are usually associated with more effective visualization; in one case of choledocholithiasis with incomplete occlusion, the ductal system was dilated despite low bilirubin. No complications with PTC were found, not even biliovenous fistula. Based on literature data, acute purulent cholangitis is the only contraindication. PTC is the method of choice in diagnosing bile duct diseases. It has been used successfully in patients with obstructive syndrome when clinical, paraclinical, and endoscopic methods were unable to differentiate intra- and extrahepatic cholestasis. For icteric patients with acute pancreatitis and complete stenosis of the hepatocholedochus, PTC is especially useful. Moreover, simultaneous liver biopsy is possible. Further diagnostic modalities include ductal pressure measurements, bacteriological and cytological examination of liver bile, hepatovenography and hepatic vein or caval angiography, and blood sampling from the hepatic vein for metabolic studies. The technical versatility of this procedure permits its use in combination with other methods.

7923 GRAY SCALE ULTRASOUND IMAGING. THE ANATOMY AND PATHOLOGY OF THE LIVER.

(Eng.) Taylor, K. J. W.; Carpenter, D. A.; Hill, C. R.; McCready, V. R. (Yale-New Haven Hosp., 789 Howard Ave., New Haven, CT 06504). *Radiology* 119(2):415-423; 1976.

A machine for gray-scale ultrasound imaging was developed and used to investigate hepatobiliary disease, especially in relation to malignancy. The machine employs a frequency of 3 MHz and a focused transducer that produces a lateral resolution of 2-3 mm over much of the beam length. In usage, the patient is supine, mineral oil is spread over the upper abdomen, and the transducer is angled under the costal margin, pointing toward the head. A simple parasagittal sector scan covers the entire right lobe of the liver, so that tumors and abscesses under the diaphragm are well-visualized. Serial sections are taken from the left of the midline to the farthest possible right of the midline. Holding the breath is advised, as it brings the liver edge below the costal margin and deflects the air-containing colon downward. In a follow-up of patients coming to laparotomy or postmortem within 3 weeks of a scan, the technique was diagnostic in 82% and contributory in an additional 10%. Unlike radionuclide scanning, few equivocal results are obtained. A major feature is the enhanced signal-to-noise ratio, so that low-level echoes are displayed. The data obtained are similar to those obtained by taking multiple cuts through the liver substance. Both diffuse and discrete pathologies are apparent. Tumor histology, which will still be required, can be obtained by liver biopsy under ultrasonic visualization.

7924 PROCTOSIGMOIDOSCOPY. AGE CRITERIA FOR EXAMINATION IN THE ASYMPTOMATIC PATIENT.

(Eng.) Corman, M. L.; Coller, J. A.; Veidenheimer, M. C. (Lahey Clinic Foundation, Boston, MA). *S. Afr. Cancer Bull.* 19(4):167-172; 1975.

A prospective study was carried out in 2,500 patients to assess the value of proctosigmoidoscopy in screening for colorectal cancer in asymptomatic patients. The patients underwent the procedure as part of a general examination, and the proctoscope was inserted to a mean length of 20 cm. Of the 2,500 patients, 1,834 were men (mean age, 51 yr) and 666 were women (mean age, 55 yr). A total of 432 lesions was found in 228 patients. Most were small and treated by fulguration without biopsy. The mean age of patients with benign polypoid lesions was 56 yr. Eight patients had adenocarcinomas; in two of these patients, carcinoma developed in a polypoid adenoma. All carcinomas occurred in patients over 50 yr of age. The authors propose the following program for the early detection of colorectal cancer: annual guaiac or orthotoluidine testing of the patient until the age of 50 yr; proctosigmoidoscopy and gastrointestinal investigations when the test is positive; stool testing for occult blood, supplemented by proctosigmoidoscopy after the age of 50 yr; proctoscopy every 2 yr thereafter; and proctoscopy annually for any patient with a history of rectal polyps or carcinoma.

7925 RELATIVE LIVER VOLUME IN STAGE I FATTY LIVER.

(Ger.) Sensing, H.; Mohr, B.; Scholtze, P. (Medizinische Poliklinik, Medizinische Akademie, Erfurt, E. Germany). *Dtsch. Gesundheitsw.* 31(18):822-825; 1976.

Correlations between radiological determination of relative liver volume and histologically confirmed degree of fatty liver (FL) are reported. The clinical sample of 127 FL patients was divided into three groups: 6 women and 19 men, average age 40 yr, with slight to moderate FL in less than 25% of the hepatocytes (group A); 11 women and 22 men, average age 40.6 yr, with moderate FL in 25%-50% of the hepatocytes (group B); and 15 women and 24 men, average age 44 yr, with massive FL in more than 50% of the hepatocytes (group C). A relative liver volume of 929.8 ml/m^2 was found in a control group of 8 women and 22 men, average age 41.3 yr. The relative liver volume in ml/m^2 for group A was 1,015.7, for group B, 1,070.1, and for group C, 1,185.3. The difference between the control value and groups B and C, and between the control value and the average of the three groups (1,102.4 ml/m^2) are significant. The difference between groups A and C is also significant There is a positive correlation between the relative liver volume and estimation of hepatomegaly by palpation. There is no correlation between relative liver volume and dye loading liver function tests. Relative liver volume is an effective measure of disease development in uncomplicated FL.

7926 A NEW DIAGNOSTIC TEST FOR PANCREATIC DISORDERS BY EXAMINATION OF PAROTID SALIVA.

(Eng.) Kakizaki, G.; Saito, T.; Soeno, T.; Sasahara, M.; Fujiwara, Y. (Akita Univ. Sch. Medicine, Akita, Japan). *Am. J. Gastroenterol.* 65(5):437-445; 1976.

The effectiveness of the parotid saliva test in the diagnosis of pancreatic diseases was studied by comparing its results with those of the pancreozymin-secretin test in 48 patients with pancreatic disorders, 82 patients with nonpancreatic diseases, and 16 healthy subjects. The patients with pancreatic disorders had a lower mean salivary output (0.274 ml/kg) and a lower mean maximum bicarbonate concentration (22.1 mEq/l) than the normal subjects and patients with nonpancreatic disorders (0.408 ml/kg and 34.4 mEq/l, resp.). An abnormal saliva test was found in 83.3% of the patients with the pancreatic disorders. Among 22 patients with pancreatic disorders and 22 patients with nonpancreatic disorders, an abnormal parotid saliva test was 88.6% accurate in diagnosing pancreatic disorders, whereas a positive pancreozymin-secretin test was only 65.9% accurate. It is concluded that the simple and rapid parotid test is sufficiently reliable to merit extensive clinical trials.

7927 THE DOUBLE-CONTRAST ENEMA: MYTHS AND MISCONCEPTIONS.

(Eng.) Laufer, I. (McMaster Univ. Medical Center, 1200 Main St., West, Hamilton, Ontario, Canada, L8S 4J9). *Gastrointest. Radiol.* 1(1):19-31; 1976.

7928 THE USE OF ENZYME ANALYSIS OF PERITONEAL BLOOD IN THE CLINICAL ASSESSMENT OF ABDOMINAL ORGAN INJURY.

(Eng.) Delany, H. M.; Moss, C. M.; Carnevale, N. (Montefiore Hosp., Albert Einstein Coll. Medicine, New York, NY). *Surg. Gynecol. Obstet.* 142(2):161-167; 1976.

GASTROINTESTINAL DISEASES

ESOPHAGUS

7968 THE DEMONSTRATION OF HETEROTOPIC GASTRIC MUCOSA IN THE ESOPHAGUS WITH ^{99m}Tc PERTECHNETATE.

(Ger.) Marowski, B.; Ambrosius, G. (II. Innere Abteilung, Stadtisches Krankenhaus Am Urban, Berlin, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 125(1):44-47; 1976.

Scintigraphic studies of the Barrett esophagus are described, and three case histories are reported. Fasting patients received 3-5 mCi ^{99m}Tc-pertechnetate i.v., and the scintigram was prepared with 400,000 impulses 20-60 min postinjection. Scintigraphy found a continuous activity concentration cranially in the distal third of the esophagus, as far as a 5-cm-long stenosis, in a 65-yr-old man with deglutition problems. Endoscopy also found a hemorrhagic, polypoid mucosa and histologically, a columnar epithelium with littoral cells. A second patient, a 65-yr-old woman, with a stenosis also in the distal third of the esophagus, but no activity concentration above the gastroesophageal transition, was found to have an adenocarcinoma. A 74-yr-old man with a 20-yr history of episodic substernal pain on eating was found to have irregular constrictions in the distal esophagus directly above the cardia and motor incoordination (repetitive, nonperistaltic contractions). The presence of heterotopic gastric mucosa in the esophagus should be suspected in cases with pertechnetate activity concentrations between the esophageal stenosis and the cardia.

7969 ENDOSCOPIC DIAGNOSIS OF BARRETT'S ESOPHAGUS.

(Eng.) Desbaillets, L. G.; Mangla, J. C. (Monroe Community Hosp., 435 East Henrietta Road, Rochester, NY 14603). *Endoscopy* 8(2):65-70; 1976.

Four cases of Barrett's esophagus in which the diagnosis was confirmed by multiple serial biopsies are presented. A 53-yr-old man presented with a history of epigastric pain, heartburn, dysphagia, and hematemesis. Barium studies revealed an ulcer with a stricture at the junction of the upper and middle thirds of the esophagus. During esophagogastroscopy, serial biopsies of the esophagus demonstrated gastric mucosa up to the level of the stricture. The patient underwent a Nissen's fundoplication; 2 weeks later, his symptoms disappeared. Two years later, biopsies revealed the persistence of the same columnar epithelium originally seen. A 51-yr-old man gave a history of frequent hematemesis and high epigastric pain. A gastrointestinal series revealed an ulcer 5 cm above the lower end of the esophagus, and multiple biopsies during endoscopy confirmed the diagnosis of Barrett's esophagus. A 75-yr-old man had had several episodes of upper gastrointestinal bleeding of unknown etiology. Esophagogastroscopy revealed marked esophagitis, along with an edematous hyperemic and friable mucosa beginning at the junction of the upper and middle thirds of the esophagus. The mucosa was similar to that seen in pseudomembranous ulcerative colitis. Barrett's esophagus was diagnosed histologically. A 63-yr-old woman presented with increasing dysphagia after a 20-yr history of intermittent dysphagia and heartburn. Barium swallow revealed a hig esophageal stricture, and esophagoscopy with multipl biopsies confirmed the diagnosis of Barrett's esophagus. She was asymptomatic 6 months after a Nissen's fundoplication. In cases of Barett's esophagus, the epithelium becomes red, congested, velvety, and friable, and there may be many linear ulcerations, whic bleed easily on contact. In all cases, the mucosa is covered with a patchy, necrotic pseudomembrane. In Barett's esophagus, the mucosal appearance may be similar to that of the colon in ulcerative colitis, pseudomembranous colitis, or *Candida albicans* esophagitis.

7970 ON INTRAMURAL ESOPHAGEAL DIVERTICULOSIS.

(Ger.) Redlich, F. H. (II. Rontgeninstitut, Radiologisches Zentrum des Stadtischen Klinikums Berlin-Buch, DDR-1115 Berlin-Buch, E. Germany). *Radiol. Diagn. (Berl.)* 17(2):217-224; 1976.

Two additional case reports of esophageal diverticulosis are added to the 10 already in the literature. An 11-yr-old girl had presented neonatally with tran scient hiatal hernia and ulcerative reflux esophagit Several years later, a paraesophageal contrast medium depot was visible at the level of the middle to lower third of the esophagus, which suggested gastric ulcer. Transthoracic hiatal repair and fixatio of the esophagus above the cardia brought some clinical amelioration. Subsequent radiology found additional depots; esophagoscopy found no ulcer or stenosis, only residual inflammation compatible with reflux. Reflux was controlled by subsequent esophagofundopexy and gastropexy. A widening of the entir suprastenotic esophagus, with peristaltic failure and persistent depot signs, was found 2 yr later. An 8.5-yr-old girl presented with dilation of the upper third of the esophagus and with paraluminal contrast media depots at stenosis level, following a useless pylorotomy. There was no sign of ulceration and *N*-butylscopolammonium bromide management was ineffective. In hospital, the child was not anorectic, and her general condition improved; at home, the child was anorectic, and the vomiting resumed. Both cases represent the effects of isolated intramural diverticula, with persistent stenosis, dyskinetic peristalsis, and transient intraesophageal pressure elevation in the lower esophagus, which persisted unchanged for years. In addition to the typical round mucosal hernias, prickle-shaped diverticula were present, which suggested some involvement of traction mechanics. The etiology in each case was clearly psychogenic.

7971 A NEW ENDOSCOPIC CLASSIFICATION OF CHRONIC ESOPHAGITIS.

(Eng.) Rasmussen, C. W. (Endoscopic Clinic, 106 S. El Molino Ave., Pasadena, CA 91101). *Am. J. Gastroenterol.* 65(5):409-415; 1976.

Five macroscopically identifiable types of esophagitis encountered in a series of 97 cases studied endoscopically are described. Forty-three were classified as erosive-ulcerative, in which histological examination revealed an infiltration of the tunica propria with epithelial damage. In 15 cases, a healing stage of the first type was seen, characterized by white nodular scars. The Barrett type of esophagitis was seen in only two cases. The fourth type was typified by shallow and mainly irregular ulcerations at the esophagogastric border or within several areas of heterotopic gastric mucosa near the junction. Symptomatically, this type is identical to the first type, and differentiation can be made only by endoscopy. A stenosing type of esophagitis was seen in 11 cases. This represents the natural outcome of several prior attacks of esophagitis. Two special types of esophagitis were not included in the above classification: that seen after ingestion of strong acid or alkali and the ulcerative esophagitis in cases with Crohn's disease.

7972 THE MALLORY-WEISS-SYNDROME: A CLINICAL STUDY OF 20 CASES. (Eng.) Knoblauch, M.; Stevka, E.; Lammli, J.; Schauwecker, H.; Deyhle, P.; Frey, P.; Sauberli, H. (Univ. Hosp., Ramistr. 100, CH-8091 Zurich, Switzerland). *Endoscopy* 8(1):5-9; 1976.

The clinical findings in 20 patients with the Mallory-Weiss syndrome (MWS) are presented, and the incidence, the basal and pentagastrin-stimulated acid secretion, and the results of esophageal manometry were studied. During a 4.5-yr period, MWS was responsible for 8% of a total of 247 acute upper gastrointestinal hemorrhages. The ratio of male to female patients was 17 to 3. All 20 patients had hematemesis, and all patients were treated with ice water lavage. Three patients received vasopressin, i.v., and four patients required surgery. Two patients died postoperatively, and five others died 2-9 months after the hemorrhage from concomitant disease. The diagnosis was made endoscopically in all cases. The lesion could not be detected radiologically. There was a history of vomiting in 12 patients. In two patients, severe coughing preceded the bleeding, and six patients had a history of alcohol abuse. The measurement of pentagastrin-stimulated acid secretion in 11 patients revealed subnormal or no acid secretion in 4 patients (1, vagotomy after operation for MWS; 2, gastrectomies); hyperacidity was found in a further patient. Esophageal manometry could be carried out in 10 patients. The lower esophageal sphincter pressure was normal (25 ± 5 mm Hg) in four patients, slightly below normal in three, and elevated in three. The results suggest that the prognosis for MWS patients is generally favorable; mortality from bleeding is only 10% and surgery is required only when conservative treatment (e.g., vasopressin infusion and Sengstaken-Blakemore tube) fails.

7973 HYPERGASTRINAEMIA AND OESOPHAGEAL STENOSIS. (Eng.) Pedrazzoli, S.; Favretti, F.; Brandtetter, S.; Militello, C.; Dodi, G.; Lise, M. (Clinica Chirurgica Generale dell'Universita di Padova, Padova, Italy). *Surg. Italy* 5(3):168-174; 1975.

Serum gastrin estimations were carried out in 15 patients with esophageal stenosis to determine whether hypergastrinemia is associated with the altered esophageal motility. The mean gastrin level in these patients was 92.1 pg/ml, which was significantly higher than that in 15 controls (33.9 pg/ml, $p<0.001$). No significant differences in gastrin level were found when the 15 patients were subdivided according to the type of stenosis (neoplastic or non-neoplastic), the site of stenosis (middle or lower third and cardia), and the severity of dysphagia; the mean gastrin level in each group was significantly higher than that in the controls. A preoperative gastric histamine-acidogram, obtained in four patients, revealed histamine-resistant achlorhydria in two patients and acid secretion in the upper limit of normal in the other two. The authors suggest that vagal stimulation, caused by esophageal distension above the stenosis, may be responsible for the high gastrin levels in these patients.

7974 ACHALASIA OF THE ESOPHAGUS. RESULTS AND SEQUELAE OF SURGICAL TREATMENT. (Fre.) Ribet, M.; Callafe, R.; Hamon, Y. (Clinique Chirurgicale Ouest, C.H.U., 59000 Lille, France). *Arch. Fr. Mal. App. Dig.* 64(8):629-637; 1975.

STOMACH

7982 POSTRESECTIONAL ANEMIA. A PREVENTABLE COMPLICATION OF TOTAL GASTRECTOMY. (Eng.) Bradley, E. L., III; Isaacs, J. (Emory Univ. Sch. Medicine, 69 Butler St. SE, Atlanta, GA 30303). *Arch. Surg.* 111(8):844-848; 1976.

Nutritional and hematologic parameters were investigated in 10 patients after total gastrectomy for complications of peptic ulcer without malignancy. Controlled balance studies were conducted during hospitalization at an average of 32 months after surgery and compared with findings after initial discharge. Even during hospitalization, 3 patients had an iron intake less than 85% of the recommended dietary allowance, and 9 of 10 had insufficient folic acid intake. Seven of ten had mild nitrogen malabsorption, but only two were in negative nitrogen balance during hospitalization. Lesser amounts of each dietary constituent, with the exception of folic acid and B_{12}, were taken in after return home, but aside from the apparent universal tendency for insufficient folic acid intake, no pattern of intake deficiency was determined. Seven of the ten were anemic in terms of decreased circulating RBC. Macrocytosis was seen in five, three of whom also had abnormally low numbers of circulating RBC. Iron deficiency was present in three. Of five patients studied during the 1st postoperative yr, four had either anemia or sideropenia, while four of five studied after the 1st postoperative yr failed to show any abnormalities in iron metabolism. One case of hemoglobinopathy was observed (hemoglobin A 66%-C 33%). Serum B_{12} levels were normal in nine, and one patient with low serum B_{12} showed clinical manifestations of B_{12} deficieny. Serum folate levels were low in three patients, but only one of these had evidence of a maturation abnormality. All ten patients exhibited malabsorption of orally administered cyanocobalamin, even when sufficient exogenous intrinsic factor was given. Reticulocytosis was not evident in eight, and only two were capable of a reticulocyte response to low numbers of circulating RBC. Erythropoietin levels were normal in five and increased in five, suggesting that an adequate stimulus for RBC production was being given to the marrow. It is concluded that postresectional anemia is mult causal, but that it is primarily nutritional.

7983 EARLY GASTRIC CARCINOMA. (Eng.) Rowland R.; Hecker, R.; Fitch, R. J.; Gibson, G. E.; Willing, R.; Jennings, W. L. (Inst. Medical and Veterinary Science, Frome Road, Box 14, Rundle St. P.O., Adelaide, South Australia 5000). *Aust. N.Z. J. Surg.* 45(4):349-354; 1975.

Seven cases of early gastric carcinoma (lesion confined to the mucosa or submucosa only) are reported Recent significant weight loss was reported by thre patients, but dyspepsia had been present for 18 months to 25 yr. Histories were indistinguishable from that of peptic ulcer. Barium meal studies wer conducted in all seven cases. Gastric ulceration was revealed in six cases, and the possibility of gastric carcinoma was raised in two cases. In thre of the six in whom endoscopy was performed, the gastric ulcers appeared benign, and in the other three there was suspicion of malignancy. In six cases, the ulcer was situated near the lesser curvature. Endoscopic biopsy revealed malignancy in all six, but a second biopsy was necessary in one patient. All patients underwent partial gastrectomy (five Billroth I and two Polya-type gastrectomies). Ther was no recurrence after follow-up of 3 to 36 months The histologically identified tumor patterns were extremely variable and included signet ring cell, colloid, undifferentiated, and well and moderately differentiated adenocarcinoma. The muscularis mucosa was invaded in four cases, but no vascular invasion was seen. The good results of early surgery are emphasized.

7984 A CONTROLLED CLINICAL TRIAL OF FLUOROURACIL PLUS IMIDAZOLE CARBOXAMIDE DIMETHYL TRIAZENO PLUS VINCRISTINE PLUS BIS-CHLOROETHYL NITROSOUREA PLUS RADIOTHERAPY IN STOMACH CANCER. (Eng Falkson, G.; Van Eden, E. B. (H.F. Verwoerd Hosp., P/Bag x169, Pretoria 0001, South Africa). *Med. Pediatr. Oncol.* 2(2):111-117; 1976.

Two regimens of combination chemotherapy and radiotherapy were compared in 59 evaluable, randomly allocated patients with inoperable or recurrent adenocarcinoma of the stomach. Group A patients received 5-fluorouracil (12.5 mg/kg/d x 5, i.v.) and group B patients received a four drug combination: 5-fluorouracil (10 mg/kg/d x 5, i.v.), 5-(3,3-dimethyl-1-triazeno)imidazole-4-carboxamide (DIC, 3 mg/kg/day x 2, i.v.), vincristine (0.025 mg/kg x 1, i.v.), and 1,3-bis(2-chloroethyl)-1-nitrosourea (1.5 mg/kg x 1, i.v.). Courses of treatment were repeated at 5-week intervals. Radiotherapy consisted of 2,000 rads ^{60}Co in 12 days, beginning on the first day of chemotherapy. Beginning on the first day of the second through the fifth course of chemotherapy, an additional 1,200 rads was administered. No life-threatening toxicity was encountered on either regimen. Toxic effects among group A patients included nausea (19), vomiting (11), diarrhea (9), stomatitis (14), fall in Hb (8), leukopenia (19), thrombocytopenia (10), and alopecia (1). Toxicity in group B patients included nausea (26), vomiting (21), diarrhea (3), stomatitis (1), fall in Hb (12), leukopenia (23), thrombocytopenia (16), and alopecia (universal). Seventeen of 31 group A patients and 10 of 28 group B patients had an objective response, while 10 group A and 7 group B patients remained unchanged. The median survivals for groups A and B were 220 and 199 days, resp. The median survival for group A responders was 222 days, compared with 410 days for group B responders. The survival times for responders plus those who did not change were 245 days for group A and 297 days for group B patients. It is concluded that with a larger group of patients, allowing for more adequate stratification, definite advantage for the four drug combination might be shown.

7985 PROBLEMS IN THE DIAGNOSIS OF PRIMARY GASTRIC STUMP CANCER AND RECURRENCES OF GASTRIC CANCER. A COMPARISON OF RADIOLOGICAL AND ENDOSCOPIC DIAGNOSIS. (Ger.) Kriedemann, E.; Rotte, K. H.; Mateev, B.; Gutz, H. J. (Zentralinstitut fur Krebsforschung der AdW der DDR-1115 Berlin-Buch, Lindenberger Weg 80, E. Germany). *Arch. Geschwulstforsch.* 45(6):552-565; 1975.

Gastroscopic and radiological findings in 13 cases of primary gastric stump carcinoma and 17 cases of its recurrence were compared. In gastric stump carcinoma radiology, seven malignancies, five questionable outcomes, and one benignity were identified. Endoscopy of the same sample found 10 malignancies, 2 doubtful results, and 1 benign process. In recurrence studies by radiology, eight malignancies, six questionable results, and three benign tumors were diagnosed, while endoscopy found eight malignancies, three doubtful diagnoses, and six benign tumors. The principal tumor site was the residual stomach, especially along the lesser curvature. The uncertain or false-negative radiological diagnoses involved tumors of the residual stomach and the anastomosis; questionable or false-negative endoscopic outcomes involved premature stenosis in the cardia or on the anastomosis. Both methods were mutually supplementary. Suspicious or controversial radiological findings are generally confirmed by gastroscopy and biopsy.

7986 MULTIPLE CARTILAGINOUS EXOSTOSES WITH POLYPOSIS OF STOMACH AND COLON: A NEW, HEREDITARY COMBINATION DIFFERENT FROM GARDNER'S SYNDROME. (Ger.) Fuchs, G. A. (Medizinische Fakultat der Technischen Hochschule, 51 Aachen, Goethestr. 27/29, W. Germany). *Dtsch. Med. Wochenschr.* 100(45):2316-2319; 1975.

The association of multiple cartilaginous exostoses and intestinal polyps in one family is reported. Two brothers, 11 and 15 yr of age, presented with epiphyseal-adjacent exostoses of the upper and lower limbs. The father had previously had a right tibial tumor, which was thought to be an interosseal exostosis. Physical examination of the boys found various skeletal anomalies in one proband with acromegaloid habitus. Urinary steroids were normal. Colon radiology found extensive sigmoid polyposis in the siblings, but none in the father. Gastric polyps (antral) were also found in the older brother. The polyposis was clinically silent. Gene analysis was not attempted; but, because of the rarity of the skeletal-gastrointestinal combination, a separate clinical entity based on linked dominant transmission is suggested.

7987 BILE REFLUX GASTRITIS: CONTRIBUTION OF INADEQUATE GASTRIC EMPTYING. (Eng.) Davidson, E. D.; Hersh, T. (Emory Univ. Clinic, 1365 Clifton Road NE, Atlanta, GA 30322). *Am. J. Surg.* 130(5):514-518; 1975.

The clinical response of 22 patients with bile reflux gastritis who had undergone operative therapy from 1973-1975 is reported. The original operation comprised vagotomy, resection, and Billroth II reconstruction in 16 patients; vagotomy, resection, and Billroth I reconstruction in 5 patients; and vagotomy-pyloroplasty in 1. Twenty-one patients underwent Roux-en-Y gastrojejunostomy and one underwent isoperistaltic jejunal interposition. Pre- and postoperatively, seven patients had clinically significant gastric atony, producing a delay in gastric emptying along with bile reflux gastritis. In the Billroth II group, 8/16 patients had a good response to operation (amelioration of symptoms and weight gain), 5 had a fair response (decrease in abdominal pain and nausea), and 3 had a poor response. Of the Billroth I patients, only one had a good result; the remaining five continued to have some gastrointestinal symptoms and had documented gastric atony and stasis. Treatment with metoclopramide resulted in an amelioration of symptoms in two patients. The pyloroplasty patient had a poor result. It is concluded that a good clinical response is obtained from the diversion of bile in patients with bile reflux gastritis who do not have significant alterations in gastric emptying. Patients with altered motility and delayed emptying experience little improvement.

7988 ANGIOGRAPHIC METHODS FOR THE CONTROL OF GASTRIC HEMORRHAGE. (Eng.) Athanasoulis, C. A. (Massachusetts General Hosp., Fruit St., Boston, MA 02114). *Am. J. Dig. Dis.* 21(2):174-181; 1976.

Angiographic methods for the control of gastric bleeding are reviewed, and the indications and possible problems that may be encountered during their application are discussed. There are two basic methods for the angiographic control of gastric bleeding: the intraarterial infusion of vasoconstricting drugs and the occlusion of the bleeding artery by embolization. The most important artery in the bleeding patient is the left gastric artery. Among 35 patients with gastric hemorrhage and an arteriogram showing definite contrast extravasation, the left gastric artery was the bleeding vessel in 29, the right gastric artery in 3, a short gastric artery in 2, and the gastroduodenal artery in 1. Vasopressin is the drug of choice in controlling gastric bleeding. For optimal results, it should be infused into the left gastric artery; when this is not possible, the celiac axis is an alternative. Hemorrhage was controlled in 82% of patients treated with vasopressin. The complication rate of arterial thrombosis at the puncture site is no higher than that in patients undergoing visceral angiography (0.02%). Arterial occlusion of the bleeding artery has been carried out using unmodified autologous clot or autologous clot with additives such as oxidized cellulose, aminocaproic acid, thrombin, or surgical gelatin. Transcatheter occlusion should be used cautiously, when an adequate collateral blood supply exists; it should not be used in conjunction with vasopressin infusions, because this may produce infarction. The author suggests that vasopressin infusion should be applied first, and if this fails to control bleeding, embolization should be considered.

7989 THE ENDOSCOPIC DIAGNOSIS OF UPPER-GASTROINTESTINAL HEMORRHAGE: CHANGING CONCEPTS OF ETIOLOGY AND MANAGEMENT. (Eng.) Katz, D.; Pitchumoni, C. S.; Thomas, E.; Antonelle, M. (120 East Prospect St., Mount Vernon, NY 10550). *Am. J. Dig. Dis.* 21(2):182-189; 1976.

Changes in the concepts of the etiology of upper gastrointestinal hemorrhage were evaluated in 1,429 patients who underwent upper gastrointestinal endoscopy between 1961 and 1974. Changes in the technique between 1961 and 1974 are described, the management is discussed, and the changing concepts in the etiology of gastrointestinal hemorrhage in other studies are reviewed. Preparation for endoscopy with ice water lavage, which was used routinely in 1961, is no longer used; aspiration alone is now used, and lavage is used only with continued massive bleeding. While endoscopy was performed within hours of admission in 1961, it is now performed only within the first 24 hr. Panendoscopes now allow the examination of the entire upper gastrointestinal tract through the duodenal bulb. Traditional barium swallow is no longer considered essential, while selective angiography is performed in endoscopically undiagnosed cases with continued bleeding. Among the 1,429 cases, acute gastric mucosal lesions (acute erosive gastritis and acute gastric ulcer) were the source of bleeding in 36.3% of episodes, while the etiology in 21.4% was chronic peptic ulcer (chronic duodenal, chronic gastric, and marginal ulcer). Bleeding esophageal varices were seen in 15.7% of the cases, miscellaneous diagnoses were established in 12.7% of the cases, and 13.9% of the cases remained undiagnosed. An analysis of the most recent 150 cases (1972-1974), utilizing only panendoscopes, demonstrated an upward shift of acute mucosal lesions (accounting for 54.1% of the cases) and a reciprocal downward shift of the incidence of chronic peptic ulcers (11.3%). This is explained by the diagnosis of acute duodenitis in cases once thought to be bleeding from chronic duodenal ulcer. A review of the literature reveals that the incidence of duodenal ulcer is relatively low compared to that noted 20 yr ago. Acute mucosal lesions, which were largely unrecognized 15 yr ago, now rank as one of the two major bleeding sources in all series.

7990 THE EFFECT OF ACUTE HYPERGLYCEMIA ON GASTRIC EMPTYING IN MAN. (Eng.) MacGregor, I. L.; Gueller, R.; Watts, H. D.; Meyer, J. H. (Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Gastroenterology* 70(2):190-196; 1976.

The effects of acute hyperglycemia on the gastric evacuation of a variety of test meals were studied in normal human subjects. Hyperglycemia was accomplished by both high- and low-load doses of i.v. glucose: 150 mg/kg as an initial bolus, followed by a constant i.v. infusion of either 5 mg/kg/min (low load) or 10 mg/kg/min (high load). The time course of plasma glucose revealed that with both loads of glucose, the blood sugar concentration began to fall after 45 min and was near fasting levels at 105 min. The i.v. glucose infusions slowed the rate at which polyethylene glycol passed the sampling site, distal to the ligament of Treitz, after a protein-fat meal ($p<0.005$ for high glucose load and $p<0.025$ for low load). The mean $T_{1/2}$ of of gastric emptying was 39.6 min for saline controls, 56.8 min for the low-glucose load, and 70.9 min for the high-glucose load. Hyperglycemia did not significantly slow the gastric emptying of a hypertonic saline meal, but it did significantly slow the emptying of a 600 mOsm meal of milk powder digest. A 600 mOsm glucose meal was emptied at a significantly slower rate ($p<0.05$) than a 600 mOsm mannitol meal, with a $T_{1/2}$ of 29.2 and 20.1 min, resp. It is concluded that hyperglycemia does exert an effect on gastric emptying, but that the effect depends on the presence of other factors which themselves slow gastric emptying.

7991 RESPONSE TO PENTAGASTRIN IN MAN. IV. DOSE-RESPONSE CHARACTERISTICS. (Eng.) Thjodleifsson, B.; Wormsley, K. G. (Medical Dept., Landspitalinn, Reykjavik, Iceland). *Acta Hepatogastroenterol. (Stuttg.)* 23(2):124-130; 1976.

To determine the kinetics of the interaction of pentagastrin with gastric secretory cells, the effects of different doses of i.v.-administered pentagastrin on gastric secretion were studied in seven subjects. The secretion of acid took up to 30 min to reach peak values during a constant rate infusion of pentagastrin (0.01, 0.5, 0.2, 1.0, or 4.0 μg/kg/hr). Consequently, both the observed and calculated maximal responses during the second 30 min of the infusions of pentagastrin were greater than during the initial 30 min. When the doses of pentagastrin were given sequentially (30 min/dose), the observed peak responses to the step test were identical with the second 30-min response to the single infusions. This is thought to be due to the lower dose rates in the step test acting as priming doses. The response to the two lowest doses of the step test were similar to the response during the first 30 min of the infusion of the single dose rates of pentagastrin, so that both the ED_{50} and the calculated maximal response for pentagastrin estimated from the step test were greater than those calculated from the single-dose infusions. The results emphasize the importance of recognizing factors that may distort the values of the calculated indices of the secretory responses to pentagastrin.

7992 ULCER SIMULATING GASTRIC CARCINOMA. II. HISTOPATHOLOGY AND SURVIVAL. (Eng.) Sipponen, P.; Hakkiluoto, A.; Lempinen, M. (Univ. Central Hosp., Haartmaninkatu 4, 00290 Helsinki 29, Finland). *Ann. Chir. Gynaecol. Fenn.* 64(1):10-17; 1975.

Histological specimens of 48 gastric carcinomas that simulated benign ulcers were reexamined to determine the depth of invasion of malignant cells, and the survival rates for gastric carcinomas invading different areas were compared. Twenty-two of the 48 benign ulcer-simulating carcinomas were adenocarcinomas, 15 were mucocellular, and 11 were anaplastic poorly differentiated forms. In 20 cases, the carcinoma fulfilled the criteria for early gastric cancer and did not extend beyond the mucosa or submucosa of the gastric wall. The 5-yr survival rate in the entire series was 63%. Among those in whom the cancer was limited to the mucosa or submucosa, the 5-yr survival was 77%, but in the advanced cancers it was only 52%. The mucocellular type had a 77% 5-yr survival, while the adenocarcinomas had a 5-yr survival of 49%. Gastric carcinomas simulating benign ulcers have the same histological types as primary gastric carcinomas. The good prognosis in these cases is attributed to the high percentage of early carcinoma.

Peptic Ulcers

8023 COMPARATIVE STUDY OF THE HOSPITAL TREATMENT OF DUODENAL ULCER UNDER ENDOSCOPICAL PROGRESS CONTROL--WITH AND WITHOUT MEDICINAL SUPPORT. (Ger.) Mittelstaedt, A.; Schwick, M. (Dept. Gastroenterologie der Inneren Abt., Augusta-Krankenhaus, Amalienstrasse 9, 4 Dusseldorf-Rath, W. Germany). *Fortschr. Med.* 94(20/21):1183-1189; 1976.

The therapeutic effect of a preparation whose active principle is deglycyrrhizinated liquorice (Caved-S) on duodenal ulcers was analyzed. Group A consisted of 15 patients receiving two tablets of Caved-S daily four times during an initial 7-day period, followed by two tablets per day three times during the next 3 weeks. Group B consisted of 15 patients receiving a commercial antacid. Fifteen patients in group C received a placebo. The doses for groups B and C followed that of group A. No patient was hyperchlorhydric, but 30% presented with concurrent gastritis. All pretreatment ulcers were in florid stages I or II. After 2 weeks, 14 patients in group A, 13 in group B, and 13 in group C showed subjective improvement, particularly in epigastric pain. Of these, three in group A and one in group B were completely asymptomatic. After 4 weeks, 13 in group A, 11 in group B, and 10 in group C, were free of complaint, while the remainder were improved. Endoscopically, 10 in group A, 9 in group B, and 7 in group C had either significantly reduced ulcers or disappearance of wall defects at the end of 2 weeks. After 4 weeks, 12 patients in group A, 10 in group B, and 9 in group C were completely healed, with well-developed cicatrices; the remainder showed significant ulcer regression. The curative curve of gastritis followed that for duodenal ulcers. Weight gain was not associated with water retention. The serum sodium, potassium, and calcium levels were not affected, and the blood pressure was unchanged. Thus, the healing rate of duodenal ulcer patients was slightly better than those who had been treated with antacids and significantly better than those patients who had been given small quantities of antacids later on. Hospitalization alone leads to ulcer healing in over 60% of the cases, which excludes the evidence of an influence of drugs.

8024 CLINICAL COURSE OF PEPTIC ULCER AND THE EFFECT OF PHARMACOTHERAPY: MULTI-INSTITUTIONAL DOUBLE-BLIND CONTROLLED STUDY. (Eng.) Yamagata, S.; Ishimori, A.; Sato, H.; Taneda, T.; Ishihara, K.; Tohei, N.; Masuda, M.; Kawai, K.; Hara, Y.; Konishi, K.; Ashizawa, S.; Nakano, H.; Fukuchi, S.; Okabe, H.; Tsuneoka, K.; Saito, Y.; Takemoto, T.; Kurokawa, K.; Niwa, H.; Kaneko, E.; Masuda, H.; Wada, T.; Sato, K.; Ogawa, N. (Tohoku Univ. Sch. Medicine, Seiryo-machi 1-1 Sendai, 980 Japan). *Gastroenterol. Jpn.* 10(4):323-341; 1975.

Comparative double-blind clinical trials were carried out in a series of 302 cases of gastric ulceration at 15 medical institutions to investigate the clinical course of peptic ulceration and the effect of N-acetyl-L-glutamine aluminum complex (KW) on this process; 213 patients completed the study. The effect of KW was compared with that of basic aluminum sucrose sulfate (UL) and of a placebo (lactose). There was a significantly higher cure rate (ulcer healing) among the inpatients (82.9%) than among the outpatients (56.7%) after 12 weeks of treatment with placebo. The cure rate for lesions in the corpus ventriculi (24.3%) was higher at 4 weeks of therapy than that of lesions at the gastric angle (9.4%); this was also true at 8 weeks (59.5% versus 40.6%) and at 12 weeks (81.1% versus 59.4%). Cumulative analysis of therapeutic responses up to 4, 8, or 12 weeks was carried out in 70 patients receiving KW (700 mg x 8/day), 74 patients receiving UL (720 mg x 8/day), and 69 cases receiving placebo. The cure rate at 12 weeks was 85.7% for the patients receiving KW, 85.1% for those receiving UL, and 71.0% for those receiving placebo. The KW cure rate was significantly higher than that of placebo ($p=0.028$) but not UL. The UL cure rate was significantly different from placebo ($p=0.032$). The difference in efficacy of these two treatments may reflect different pharmacologic actions.

SMALL INTESTINE

055 THE HISTOLOGICAL CLASSIFICATION OF DUODENITIS IN FIBREOPTIC BIOPSY SPECIMENS.

Eng.) Whitehead, R.; Roca, M.; Meikle, D. D.;
kinner, J.; Truelove, S. C. (Finders Medical Centre,
edford Park, SA 5042, Australia). *Digestion* 13(3):
29-136; 1975.

uring an investigation of upper gastrointestinal
iseases by fiberoptic endoscopy, 747 duodenal biopsy
pecimens were examined, and this material was used
o develop a classification system for nonspecific
uodenitis. The specimens were obtained from 396
ubjects, including healthy volunteers and patients
ith nonulcer dyspepsia, hiatus hernia, gastric ulcer,
uodenal ulcer, anemia and gastrointestinal bleeding
f unknown etiology, gastric neoplasms, pernicious
nemia, postgastrectomy, postgastroenterostomy, post-
agotomy and pyloroplasty, cholangitis, and self-
oisoning. The specimens were obtained from the
uodenal cap (348 specimens), proximal descending
uodenum (220), distal descending duodenum beyond
he ampulla (145), and horizontal duodenum (34). Mild
uodenitis was characterized by no significant alter-
tions in the general morphology; the superficial
pithelium was normal in height, but sometimes con-
ained an excess of lymphocytes. The main histolo-
ical feature was an excessive cellularity of the
amina propria, with or without lymphoid aggregates.
Moderate duodenitis was characterized by increased
ellularity of the lamina propria and abnormalities
f the superficial epithelium. The most severe grade
f duodenitis was characterized by the critical fea-
ture of erosion of the abnormal epithelium. This
as invariably associated with complete effacement
nd loss of the villous processes and the heaviest
egree of inflammatory cell infiltration. In nine
ormal control biopsies and nine cases from each of
the three grades of duodenitis, a quantitative estimation of the surface to volume ratio and the number of cells in the lamina propria was made. Between the groups, the differences in surface to volume ratio and in the cellularity of the lamina propria were statistically significant. This study shows that a simple subjective grading of duodenitis is possible, and quantitative methods confirm its accuracy.

8056 JEJUNOILEAL BYPASS: ROENTGENOGRAPHIC OBSERVATIONS.

(Eng.) Balthazar, E. J.; Goldfine, S. (New York Medical Coll., Flower-Fifth Ave. Hosps., 1249 Fifth Ave., New York, NY 10029). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 125(1): 138-142; 1975.

The rationale and surgical procedures for intestinal bypass operations in the management of morbid obesity are outlined, and the roentgenographic appearance of the gastrointestinal tract postsurgery is discussed. End-to-side anastomoses of jejunum to colon represented the first approach in the early sixties, but these were associated with frequent complications, including death. End-to-side jejunoileal anastomosis from a point 14 inches from the ligament of Treitz to 4 inches above the ileocecal valve, coupled with closure of the proximal end of the bypassed intestine, have resulted in an average weight loss of 130 pounds that plateaus after 3 yr. A third procedure involves an end-to-end jejunoileal anastomosis from a point 12 inches distal to the ligament of Treitz to 12 inches proximal to the ileocecal valve. The proximal end of the bypassed intestine is closed, and the distal end is anastomosed to the transverse or sigmoid colon for draining purposes. Good results have been claimed, because of an ensuing gradual and steady weight loss. The reason for the weight loss to stop past the third year is enlargement of the small bowel and hypertrophy of the mucosal folds, with concomitant jejunization of the terminal ileum. In roentgenologic evaluations of the postoperative bowel, several features are looked for: a transit time from pylorus to cecum of 5-10 min, the approximate length of the functioning small bowel, the degree of dilatation and mucosal hypertrophy, the type of anastomosis, and the reflux into the bypassed ileum.

8057 FASTING AND STIMULATED SERUM GASTRIN LEVELS IN HUMANS FOLLOWING JEJUNO-ILEAL BYPASS.

(Eng.) Coyle, J. J.; Schwartz, M. Z.; Eisenberg, M. M.; Varco, R. L.; Buchwald, H. (Dept. Surgery, Univ. Minnesota Hosp., Box 290, Minneapolis, MN 55455). *J. Surg. Res.* 20(4):365-368; 1976.

Serum gastrin levels both in the fasting state and following a standard test meal were studied in nine patients who had undergone jejunoileal bypass for morbid obesity 1 yr previously and in nine normal controls. After an overnight fast, serum samples were drawn, and then all subjects ate a standard 16-g protein meal. Serum samples were again obtained at several intervals from 5 min to 2 hr after the start of the meal, and serum gastrin levels were determined by radioimmunoassay. There was no statistically significant difference (at the $p<0.05$ level) between controls and patients in fasting or peak-response levels of serum gastrin or in the integrated gastrin response to the meal. Because the significant increases in fasting and peak response levels of serum gastrin in humans following massive small bowel resection cannot be demonstrated in humans following massive small bowel bypass, it is concluded that the bypassed small intestine may retain a role in gastrin metabolism.

8058 LIVER DYSFUNCTION FOLLOWING SMALL-BOWEL BYPASS FOR OBESITY: NONOPERATIVE TREATMENT OF FATTY METAMORPHOSIS WITH PARENTERAL HYPERALIMENTATION.

(Eng.) Ames, F. C.; Copeland, E. M.; Leeb, D. C.; Moore, D. L.; Dudrick, S. J. (M.D. Anderson Hosp., Houston, TX). *JAMA* 235(12):1249-1252; 1976.

The clinical and metabolic course of an obese man in whom jaundice and fatty metamorphosis (steatosis) of the liver developed 5 months after jejunoileal bypass is described. The patient initially weighed 172.4 kg; at the time of the liver dysfunction, he weighed 121.6 kg. The patient became weak, anorectic, nauseated, and jaundiced. Abnormal laboratory values included a serum bilirubin level of 8.9 mg/100 ml; SGOT, 125 U/ml; and serum albumin, 1.5 g/100 ml. Percutaneous needle liver biopsy specimen demonstrated extreme fatty infiltration with bile stasis. Intravenous hyperalimentation therapy began with a continuous infusion of a 4.25% crystalline amino acid and 25% dextrose solution and continued after stabilization at 80 ml/hr (2,000 kcal/day). The patient was allowed a high-protein, low-carbohydrate diet. After 75 days of therapy, the laboratory values were SGOT, 25 U/ml; serum bilirubin, 2 mg/100 ml; albumin, 3.8 g/100 ml; and total serum proteins, 6.9 g/100 ml. Biopsy showed a decrease in fatty infiltration and bile stasis and an improvement in the appearance of hepatocytes, but early periportal fibrosis. The patient was discharged weighing 112.5 kg, toleratin a high-protein, low-carbohydrate diet, and receivin no medication other than therapeutic vitamins. A repeat biopsy several months later showed a further decrease in fatty infiltration but persistent periportal fibrosis. The steatosis and dysfunction wer probably caused by the preferential absorption of carbohydrate in the remaining small bowel, with resulting protein starvation. The results show that this treatment offers sufficiently balanced nutritio to support liver metabolism, regeneration, and fat mobilization with continued weight loss.

8059 THE CONTINENT ILEOSTOMY AND THE ISOLATED ILEAL BLADDER.

(Eng.) Madigan, M. R. (Bishop's Stortford Hosp., Herts, England). *Ann. R. Coll. Surg. Engl.* 58(1):62-69; 1976.

The details of the Kock procedure are summarized, an treatment results with 19 cases are briefly reported The technique is contraindicated in the presence of Crohn's disease, fulminating ulcerative colitis, or high dose steroid therapy. In nine cases, a conventional ileostomy was converted to a continent reservoir, and in 10 cases, total proctocolectomy and ileal reservoir was done as a primary procedure. Seventeen of the 19 eventually had satisfactory, competent reservoirs. Twelve had no complications. Among the complications, four had leaking valves, which were reoperated and were continent, and one had a leaking reservoir, which was sutured and normal. There was one operative death, probably due to distal ileal ischemia, and one patient had a leaking valve which was reoperated elsewhere. The complications common to any major surgical procedure or peculiar to ulcerative colitis were not increased in the presence of an ileal reservoir. It is concluded that this procedure is a safe one and that it has several advantages to the patient.

8060 INTESTINAL LYMPHANGIECTASIA: THE VARIABILITY OF PRESENTATION. A STUDY OF FIVE CASES.

(Eng.) Roberts, S. H.; Douglas, A. P. (Royal Victoria Infirmary, Newcastle upon Tyne, NE1 4LP England). *Q. J. Med.* 45(177):39-48; 1976.

Five cases of intestinal lymphangiectasia are described. All had variable protein loss from the gut, and in four, the diagnosis was first suggested by jejunal biopsy. A 22-yr-old woman presented with a history of anemia and a recent onset of peripheral edema. The protein loss from the bowel was 12% of an administered dose (normal<0.8%). A jejunal biopsy was normal, but lymphangiography revealed slow passage into the thoracic duct. The patient had an excellent response to a low-fat diet supplemented with medium chain triglycerides. The second patient, a 21-yr-old woman, developed vomiting, weight loss, and episodic diarrhea. Protein loss was 5.5%, and bowel radiography showed dilated lymphatics, which were confirmed on jejunal biopsy and lymphangiogram. She experienced full symptomatic recovery on treatment with diuretics and vitamins. Protein loss continued during remission. A 15-yr-old girl presented with nephrotic syndrome following a streptococcal infection. Corticosteroid therapy was not helpful, and she was treated with diuretics alone for 10 yr. During the next 4 yr, she was hospitalized several times for complaints related to her glomerulonephritis. At age 34, a jejunal biopsy revealed distended central lacteals in two villi, and protein loss into the bowel was 3.1%. She died 1 yr later from left ventricular failure and septicemia. At autopsy, there was no evidence of widespread lymphatic abnormalities. A 48-yr-old woman presented with malaise, diarrhea, and weight loss. At sigmoidoscopy, the mucosa was inflamed and friable. Some villi in the jejunal biopsy showed dilated lymphatic vessels. Protein loss from the gut was 1.7%. She had a good response to treatment with blood transfusions, low-fat diet, medium chain triglycerides, and oral iron and vitamin supplements. A 3-yr-old boy developed diarrhea, and at age 8, steatorrhea was demonstrated and a diagnosis of cystic fibrosis was made. Jejunal biopsy showed dilated lymphatics, and protein loss from the bowel was 2%. On treatment with antibiotics, low-fat diet, and medium chain triglycerides, he gained weight and the diarrhea ceased. The conditions of four of these five patients symptomatically improved simply by the recognition and nonspecific treatment of intestinal lymphangiectasia. The results suggest the possibility that this condition may exist in a mild form in patients with protein-losing enteropathy.

8061 INTESTINAL AND PERITONEAL TUBERCULOSIS: REPORT OF TWO CASES. (Eng.) Fraki, O.; Peltokallio, P. (Second Dept. Surgery, Univ. Helsinki, Haartmanink 4, 00290, Helsinki 29, Finland). *Dis. Colon Rectum* 18(8):685-693; 1975.

The incidence, treatment, and clinical findings of 107 cases of abdominal tuberculosis are reviewed, and the case reports of two patients with intestinal tuberculosis are presented. In the entire series, there were 36 cases of intestinal tuberculosis, 15 occurring in the ileocecal region, 5 in the cecum, 13 in the small intestine, and 2 in the rectum; in the remaining case, a tuberculosis ulcer occurred in the duodenum. The symptoms included abdominal pain, weight loss, vomiting, diarrhea, constipation, and fever. A palpable tumor occurred in 87% of the cases. X-ray studies revealed small intestinal strictures in many cases. Resection was the most important form of therapy. Right hemicolectomy was performed in 85% of the patients with ileocecal or cecal tuberculosis. Histological examination of the bowel wall in all cases showed typical tubercles with epithelioid cells, giant Langerhans cells, a peripheral zone of inflammatory cells, and central caseation. Three patients died postoperatively, and three others died 1-3 yr postoperatively of recurrent abdominal tuberculosis. The case of a 54-yr-old woman with hemorrhage from a jejunal ulcer is presented. The patient recovered after emergency surgery and treatment with streptomycin, isoniazid, and rifampin. A second patient, a 64-yr-old woman, presented with recurrent bowel obstruction 12 and 23 yr after a side-to-side anastomosis. The anastomosis was resected and another one constructed. Histologic examination of the jejunal biopsy showed tuberculous granulomas in the mucosa, submucosa, muscle layer, and serosa. The patient recovered after antituberculosis therapy. Sixty-one patients had peritoneal tuberculosis. The most frequent symptom was abdominal pain, and a palpable tumor occurred in 25% of the cases. At surgery in 51 patients, peritoneal tubercles occurred in 38, ascites in 34, adhesions in 29, and small bowel obstruction in 5. The operative mortality was 7.8%. Ten patients had tuberculosis in other abdominal sites, including the mesenteric and retroperitoneal lymph nodes (7 cases), spleen (1), and liver (2). Good results are obtained with chemotherapy for both intestinal and peritoneal tuberculosis. The complications (e.g., obstruction) should be surgically treated; resection is the surgical procedure of choice.

Malabsorption

8087 ABNORMAL MICELLE FORMATION IN VARIOUS MALABSORPTION SYNDROMES. (Eng.) Ishikawa, M.; Masamune, O.; Yamada, H.; Takahashi, T.; Matsuura, S.; Torihata, K.; Gonai, T.; Nagasaki, A.; Tsuboi, M.; Yamagata, S. (Yamagata Univ. Sch. Med., Yamagata, Japan). *Tohoku J. Exp. Med.* 118(Suppl.): 89-95; 1976.

To clarify the relation between micelle-forming factors and the degree of micelle formation, the upper intestinal contents of 12 normal subjects and 18 patients with steatorrhea (6 cases of chronic pancreatitis, 4 of pancreatectomy, 4 of ileal disease, and 4 of blind-loop syndrome) were analyzed after a Borgstrom test meal. In normal subjects, the mean proportion of total fat in the micellar phase was 79.9%, the mean concentration of conjugated bile salts was 7.7 mM, and the ratio of glycine conjugates to taurine conjugates was 2.3. There were no unconjugated bile salts in normal individuals, and the mean lipase concentration, polyethyleneglycol (PEG) concentration, and pH were 198 U, 32.2, and 6.7, resp. The ratio of free fatty acids and monoglyceride to total fat was 73.4%. In chronic pancreatitis and pancreatectomy, 58 ± 21.4% and 23 ± 19.2% of the total fat were hydrolyzed to fatty acid and monoglyceride, resp. The proportion of fat in the micellar phase was 56%, and the lipase concentration was 78 U in chronic pancreatitis; corresponding values in pancreatectomy were 24.9% and 33.9%. Bile salts and pH were normal. In ileal diseases, 41.9% of the fat was in the micellar phase, and the concentration of conjugated bile salts was 1.8 mM. In blind-loop syndrome, the ratio of fat contents in the micellar phase to total fat was relatively low, and the lipase concentration was similarly reduced (93.5 U). The concentration of total bile salts was 16.5 mM/l; unconjugated bile salts were detected by thin layer chromatography. The results demonstrate that the mixing of the test meal with pancreatic juice, bile, and the proper intestinal juice is well-coordinated in normal subjects.

8088 IMMUNOLOGICAL PHENOMENA IN THE JEJUNUM AND SERUM AFTER REINTRODUCTION OF DIETARY GLUTEN IN CHILDREN WITH TREATED COELIAC DISEASE. (Eng.) Lancaster-Smith, M.; Packer, S.; Kumar, P. J.; Harries, J. T. (Hosp. Sick Children, Great Ormond St., London WC1, England). *J. Clin. Pathol.* 29(7):592-597; 1976.

Immunological changes in the jejunal mucosa and serum were studied in 22 treated celiac children in whom the diagnosis had been made without biopsy between 6 months and 5 yr and who at the time of study were 5-16.5 yr old. Sixteen children had been on a gluten-free diet from 1.5 to 13 yr, and six admitted to consuming varying amounts of gluten immediately before the study. Fifteen had proven celiac disease based on the jejunal response to gluten (10 g/day as wheat protein for 3 months), and the remaining seven had a normal mucosa and no clinical or biochemical evidence of celiac disease, even after a substantial gluten intake from 1 to 12 yr. The numbers of jejunal mucosal immunoglobin A (IgA) and IgG-containing cells in celiac patients on gluten-free diets did not differ from controls. The numbers of these cells in patients on gluten-containing diets were significantly greater than controls ($p<0.05$ for IgA cells and $p<0.002$ for IgG cells). In 10 patients studied serially, there was a significant increase in the numbers of these cells after 3 months on a gluten-containing diet ($p<0.01$ for IgA cells and $p<0.05$ for IgG cells). Greater numbers of these cells were also seen in biopsies with villous atrophy than in celiac biopsies with normal morphology ($p<0.01$ for IgA and $p<0.05$ for IgG). The numbers of IgM cells were greater than in controls, even in celiacs on a gluten-free diet ($p<0.01$), and this number increased in patients on gluten-containing diets ($p<0.002$ compared to controls). There was an increase in IgM cells in the 10 patients studied serially during 3 months on a gluten-containing diet. In three serially studied subjects who had normal jejunal morphology after 3 months on a gluten-containing diet, there was no significant change in any of the three cell types. Basement membrane staining with anti-IgA serum occurred in celiacs and was most intense in untreated patients. Serum concentrations of IgA, IgG, and IgM in celiac patients did not differ from controls, regardless of diet. After 3 months on a gluten-containing diet, there was no significant change in serum IgA and IgG, but the level of IgM fell significantly ($p<0.01$). It is suggested that both IgA and IgM systems are important in the immunopathogenesis of the small intestinal lesion of childhood celiac disease.

8089 REGRESSIVE MYOPATHY WITH MYASTHENIC SYNDROME IN IDIOPATHIC GLUTEN ENTEROPATHY. (Ger.) Gundlach, H.-J.; Ernst, K. (Universitats-Nervenklinik Rostock, DDR-25 Rostock-Gehlsdorf, Gehlsheimer Strasse 20, E. Germany). *Psychiatr. Neurol. Med. Psychol. (Leipz.)* 27(4):225-230; 1975.

The case history of frank myopathy in a patient with protracted idiopathic sprue is presented. A 30-yr-old woman with an unexceptional family history presented with marked, persistent diarrhea following parturition. Endiaron brought transient relief. Asthenia in the extremities and locomotor difficulties began within 3 yr. Glycine, vitamin B complex, and pepsacid, administered under suspicion of sprue, elicited transient relief. Progressive muscle dystrophy was established 12 months later, with intractable asthenia. A diagnosis of gluten enteropathy followed histological confirmation of villous atrophy in the small bowel, depressed serum potassium and calcium levels, and steatorrhea. General amelioration was established by electrolyte, iron, and vitamin substitution therapy. The proximal myasthenia, whose histological picture included only fiber swelling but no destructive changes or interstitial proliferation, regressed under management of the enteropathy.

LARGE INTESTINE

8102 CLINICAL PRESENTATION OF DISEASES OF THE LARGE BOWEL: A DETAILED STUDY OF 642 PATIENTS. (Eng.) Staniland, J. R.; Ditchburn, J.; de Dombal, F. T. (General Infirmary, Leeds LS1 3EX, England). *Gastroenterology* 70(1):22-28; 1976.

The symptoms and clinical findings in 642 patients with a variety of lower gastrointestinal disorders, including rectosigmoid cancer (131 patients), diverticular disease (265), right-sided colonic cancer (50), ileocecal Crohn's disease (61), colonic Crohn's disease (50), and ulcerative colitis (85) were reviewed. Ninety percent of the patients with diverticular disease complained of pain at the time of hospitalization; the same was true of 87% of the patients with ileocecal Crohn's disease, 80% of those with carcinoma of the cecum or ascending colon, 55% of those with ulcerative colitis, 58% of those with colonic Crohn's disease, and 34% of those with rectosigmoid cancer. Half of the patients with ileocecal Crohn's disease complained of pain in the right half or center of the abdomen, while 28% of the patients with right-sided colonic cancer (usually cecal) complained of pain in the right lower quadrant, and

28% of patients with diverticular disease complained of left lower quadrant pain. Patients with colitis or rectosigmoid cancer usually had intermittent pain related to defecation, whereas the patients with diverticular disease, ileocecal Crohn's disease, and right-sided colonic cancer had steady or colicky pain. Almost half of the patients with lower gastrointestinal disease complained of symptoms referable to the upper gastrointestinal tract: 73% of the patients with diverticular disease, 30% of those with ileocecal Crohn's disease and right-sided colonic cancer, and over 20% of those with colitis had nausea; nearly 50% of the patients with active diverticular disease had vomiting; and approximately half of all the patients had anorexia. Over half of the patients with right-sided cancer and over three-fourths of the patients with ileocecal Crohn's disease had a normal and unaltered bowel frequency. Twenty-three patients with diverticular disease, 14% of those with ileocecal Crohn's disease, and 12% of patients with right-sided colonic cancer had increased urinary frequency. Approximately 40% of the patients with large bowel cancer had undergone previous, unrelated abdominal surgery. At the physical examination, the presence of abdominal tenderness or a palpable abdominal mass was helpful in a discriminate diagnostic sense. An analysis of the results of sigmoidoscopy and rectal examination revealed that, although the classical changes of Crohn's disease may eventually develop, they may not develop early in the course of the illness and are of limited diagnostic value. It is suggested that the data obtained in the present study may be beneficial in the diagnosis of large bowel diseases.

8103 FURTHER STUDIES ON LIPID-CHEMICAL DIFFERENCES BETWEEN CANCEROUS AND ADENOMATOUS POLYPOUS TISSUES IN THE HUMAN LARGE INTESTINE. (Eng.) Nakazawa, I.; Yamagata, S.; Watanabe, H. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 118(Suppl.):117-125; 1976.

The tissues from 17 patients with colonic cancer were compared biochemically with those from 18 patients with adenomatous polyps of the colon. The total lipids in both tissues from the cancerous and benign lesions and from the normal tissue surrounding the lesions were separated into triglycerides and phospholipids by thin-layer chromatography. The fatty acid content of the total lipids, determined by gas-liquid chromatography, was decreased in 71% of the tissues from cancerous lesions, in comparison with the fatty acid content in the normal tissue surrounding the lesions. The fatty acid content was increased in 80% of the adenomatous polyp tissues. The fatty acid content of phospholipid was decreased in 60% of the cancerous tissues, but was increased in 71% of the adenomatous polyp tissues, compared with the control tissues. The fatty acid content of triglyceride in the cancerous lesions was decreased in all cases and in 93% of the adenomatous polyp tissues. This may be due to increased utilization of triglyceride in rapidly proliferating cancerous tissues or to a depressed biosynthesis of triglyceride in cancerous tissues. The ratios of the phospholipid fatty acid content to the triglyceride fatty acid content in the neoplastic tissues were always higher than those of the control tissue in both benign and cancerous tissues. The mean deviation rate (DR, the percentage of fatty acid in the morbid tissue/percentage of fatty acid in the control tissue) for $C_{14:0}$ in the cancerous tissues (2.307) was significantly increased in comparison with that in the benign tissues (1.001). The DR value of $C_{20:4}$ in the cancerous tissue (0.762) was decreased in comparison with that in the benign tissues (1.003). The ratio of the DR value of $C_{14:0}$ to $C_{20:4}$ ranged from 2.064 to 4.125 for 10 cancerous tissues and from 0.393 to 1.856 for 16 benign tissues. This ratio may be used to distinquish cancer and adenomatous polyps in the large intestine.

LARGE INTESTINE

Ulcerative Colitis

8148 STUDIES IN ULCERATIVE COLITIS PATIENTS BY MMPI SAARBRUCKEN. (Ger.) Liedtke, R.; Tschirch, L.; Zepf, S. (II. Medizinische Klinik der Universitat, Metzstrasse 53/57, D-2300 Kiel, W. Germany). *Med. Klin.* 71(19):807-813; 1976.

Personality traits in ulcerative colitis patients are contrasted with traits in normal subjects by the Minnesota Multiphasic Personality Inventory (MMPI) test. The clinical sample included 18 men and 12 women, the majority of whom were 31-45 yr of age. Two-thirds of the colitis patients were 21-35 yr of age, and had been ill at least 10 yr. A control group exactly matched the colitis group in number, sex, age, family status, education, occupational status, and income. The rough values of the control group and the colitis group were compared without K-correction for the 14 standard scales of the MMPI. All group differences were insignificant ($p>0.05$) except four. The scale for hypochondria, introversion, and paranoia were $p<0.05$, and depression was $p<0.01$. To test whether these behavioral variables might be reactions to, rather than stimuli of, ulcerative colitis, the sample was divided into three groups of different durations of the colitis and the variables were compared. There was no correlation between the variables and the duration of illness.

8149 ULCERATIVE COLITIS IN THE JEWISH POPULATION OF TEL-AVIV YAFO III. CLINICAL COURSE. (Eng.) Gilat, T.; Lilos, P.; Zemishlany, Z.; Ribak, J.; Benaroya, Y. (Ichilov Hosp., Tel-Aviv, Israel). *Gastroenterology* 70(1):14-19; 1976.

The clinical course of ulcerative colitis was studied in 504 Jewish patients from the Tel-Aviv area, and further information on the geographical and ethnic variations of the disease was obtained. Forty-nine percent of the patients were Ashkenazi Jews. The following symptoms were initially recorded: blood in the stools, 6.2%; diarrhea, 13.9%; or both, 75.4%. Sigmoidoscopy showed bleeding in 370 cases, ulcers in 235, and mucosal changes (inflammation, edema, and granularity) in 440. At the initial examination, about half of the known cases had distal disease, and about one-tenth had universal disease. At the final examination, slightly over 25% had distal disease, and slightly less than 25% had universal disease. The incidence of colonic carcinoma in these patients was low (0.6%). Toxic megacolon occurred in 2.4% and perforation in 1.4%. Pseudopolyps occurred in 13.9% (5% in distal disease, 16.8% in substantial disease, and 40.6% in universal disease). Iron deficiency was documented in 28.8% of the cases, and anemia was found in 40.7%. The extracolonic manifestations included: skin disease, 2.6%; eye disease, 0.6%; liver disease, 3.2%; and arthritis, 4.8%. The incidence of liver disease correlated with the increased extent of the disease. Duodenal ulcer occurred in 7.1% of the cases, asthma in 2.2%, psychosis in 4.0%, and urinary calculi in 3.2%. Severe attacks occurred at one time or another during the course of the disease in 21.6% of the cases; the disease course was estimated to be mild in 63.3%, moderate in 22.4%, and severe in 14.1%. The results suggest that the disease process is progressive or stationary; there is hardly ever regression. The data are compared with other published series of ulcerative colitis occurring in patients in different geographical areas.

8150 IMMUNOGLOBULIN-CONTAINING CELLS IN THE INTESTINAL MUCOSA IN ULCERATIVE COLITIS. (Eng.) Tsuchiya, M.; Asakura, H.; Shimabukuro, K.; Morita, A.; Hibi, T.; Saito, H. (Dept. Internal Medicine, Sch. Medicine, Keio Univ., 35 Shinanomachi, Shinjuku-ku, Tokyo, Japan). *Gastroenterol. Jpn.* 9(4):385-394; 1975.

The distribution of immunoglobulin (Ig)-containing cells in the colonic mucosa of seven thymectomized patients with ulcerative colitis is described. All patients underwent roentgenological examination of the colon following barium enema, endoscopic examination, serum Ig assay, and biopsy to determine the distribution of Ig-containing cells in the colonic mucosa. All cases showed a distribution pattern of IgG- and IgM-containing cells that was similar to that of normal controls. There was an increased number of IgA-containing cells in 2/7, but no significant change in intramucosal distribution. There was no significant correlation between the number of IgG-, IgA-, or IgM-containing cells and stage of disease, area of involvement, or degree of severity. Also, no significant relation could be found among the distribution of Ig-containing cells in the mucosa and the roentgenologic or endoscopic findings of the colon, or serum Ig levels. Thus, the study failed to reveal a definite change or pattern in serum and tissue Ig, the principal constituents of humoral immunity, that could be associated with ulcerative colitis.

8151 EPITHELIAL DYSPLASIA IN ULCERATIVE COLITIS. HISTOLOGICAL POSSIBILITY FOR THE EARLY DIAGNOSIS OF "COLITIS" CARCINOMA. (Ger.) Otto, H. F.; Gebbers, J.-O. (Pathologisches Institut der Universitat Hamburg, Martinistrasse 52, D-2000 Hamburg, W. Germany). *Langenbecks Arch. Chir.* 341(2): 99-110; 1976.

The modalities of dysplastic epithelial modification found in rectocolonic biopsies are described and their prognostic potential relative to frank carcinoma in prolonged colitis is examined. Of 249 ulcerative colitis cases, 20 were selected with onset before 21 yr of age and with a duration of more than 10 yr. Epithelial dysplasia (ED) could be followed by rectal biopsy in seven cases, including four with multicentric carcinoma (CA) and three with multifocal ED. In one case of sigmoid CA, the rectal ED was moderately acute and, in another case, the rectal ED was slight and the colonic ED was acute (carcinoma *in situ*). Rectal and colonic ED were both moderately acute in a patient with CA of the sigmoid nd left splenic flexure. One case of transverse olon CA was associated with acute rectal ED (carinoma *in situ*). Three types of ED were established: olypoid (villous) dysplasia, ED of the crypt epihelium, and epidermoid metaplasia with cellular typia. Type 1 involves villous-type proliferation, ith frequent mitoses and a cell atypia resulting rom arrested regeneration on the border of inflamatory-ulcerative lesions; all mucous-forming poential is lost. The second type is demonstrable nly by histology and is assumed to represent the eginning of undifferentiated colitis CA. Type 1 is ssumed to be the precursor of polypoid adenocarcioma as the intercryptal stroma usually exhibits eactive hyperlasia. The third type involves a ultilevel epidermoid, differentiated epithelium, hich remains mucogenic, both in the crypts and on he surface. No invasive CA was ever associated ith the third type and thus, this type may represent n "indirect" or transitional metaplastic type.

152 EXPERIMENTAL ULCERATIVE DISEASE OF THE COLON. (Eng.) Watt, J.; Marcus, R. (Univ. iverpool, New Medical Sch., Ashton St., P.O. Box 47, Liverpool L69 3BX, England). *Methods Achiev. xp. Pathol.* 7:56-71; 1975.

n experimental guinea pig model for human ulceraive colitis is described. Ulceration is induced by eeding aqueous solutions of carrageenan from the ed seaweed *Eucheuma spinosum*. Local ulceration is roduced by the administration of 1% undegraded carrageenan over a period of 6 weeks, during which time he animals remain in good general condition. After weeks, about 50% of the animals have ulceration, nd after 6 weeks, all animals are affected. The esions are mainly in the cecum, but a few may be ound in the adjacent proximal colon. A more extensive type of ulceration results from oral administration of 5% degraded carrageenan over a period of weeks. The general condition of the animals deteriorates with this dose, and weight loss becomes apparent after 2 weeks, and may amount to 15-25% after weeks. The stool becomes loose after 1 week and contains occult blood within 2-3 weeks. Ulceration begins in the cecum between the 2nd and 3rd week and is widespread throughout the large intestine in all animals by the end of the 4th week. The ulcerative lesions produced by degraded or undegraded carrageenan display generally similar histological features, with infiltration of polymorphonuclear leukocytes and macrophages, which show metachromasia of the cytoplasm in toluidine blue-stained sections. There may be mucosal edema, capillary congestion, and extravasation of RBC. The liver may show focal fatty change and, less commonly, periportal round cell infiltration. In the kidney, hydropic vacuolation of the epithelium of the convoluted tubules is seen, as well as metachromasia in the stroma of the pyrimids and in the cytoplasm of the epithelium of the tubules and collecting ducts. The similarities of the clinico-pathological features of the model and of human ulcerative colitis are discussed. The etiology is thought to involve a direct local action in the bowel.

PANCREAS

8158 THE ACIDITY AND PEPTIC ACTIVITY OF GASTRIC JUICE IN HEALTHY CHILDREN AND IN CHILDREN SUFFERING FROM CYSTIC FIBROSIS OF THE PANCREAS. (Ger.) Fieber, M.; Meschede, R.; Tolckmitt, W. (Zentrum fur Kinderheilkunde, Klinikum der Justus-Liebig-Universitat, D-6300 Giessen, Feulgenstrasse 12, W. Germany). *Z. Kinderheilkd.* 120(3):199-209; 1975.

The acidity and proteolytic activity of gastric juice in cystic fibrosis (CF) children was assayed to determine whether gastric function is suppressed or compensatorily increased relative to healthy children. The sample consisted of 10 CF patients and 20 normal children of corresponding age. Using a partially hierarchical analysis of variance, the slope of the curves for the volume of gastric juice, amount of acid, and peptic activity varied significantly between groups; there was no difference in pH. The basal gastric volume increased with age in both groups. Pentagastrin-stimulated maximal gastric volume also varied directly with age, but the CF values were significantly lower. There was no group difference in peak volume output. Maximal acid secretion, but not basal acid output, increased with age. There was no variation between groups in maximal gastric volume, basal acid output, or peak acid output. Basal peptic activity increased significantly with age only in the control group, but the maximal peptic activity was age-dependent in both groups. Peak peptic output showed no group difference. Although the maximal gastric volume was smaller in the CF group, there is no evidence that gastric digestive function is abnormal.

8159 PANCREATIC ABSCESS: A CRITICAL ANALYSIS OF 113 CASES. (Eng.) Camer, S. J.; Tan, E. G. C.; Warren, K. W.; Braasch, J. W. (Lemuel Shattuck Hosp., Boston, MA). *Lahey Clin. Found. Bull.* 25(1):1-10; 1975.

A critical analysis of 113 cases of pancreatic abscess was made to define the diagnostic, therapeutic, and prognostic parameters important to management. The most common symptoms, signs, and laboratory data for patients with acute (37), chronic (29), and postoperative (47) pancreatitis included: epigastric pain, fever, anorexia, weight loss, tenderness, abdominal mass, anemia, leukocytosis, and serum amylase elevation; distention and jaundice were found more often in the postoperative cases. Culture reports were positive in 88/96; *Escherichia coli* was recovered in 45%. Radiographic examination of the chest disclosed pleural effusion, diaphragmatic elevation, and basilar atelectasis in 38 patients. There was evidence of pancreatic enlargement in 40/46 patients undergoing contrast studies. Pancreatitis and pancreatic necrosis were found in conjunction with all abscesses; a single cavity was found in 39 patients. In 6/113 the abscess was first seen at autopsy. The rest (107) underwent operative drainage. Mortalities included 5 patients in the acute group, 3 in the chronic group, and 11 in the postoperative group. Complications were varied and often multiple, notably, septicemia, renal failure, pleural effusion, wound abscess, diabetes, gastric retention, ileus, and fistula. Twelve of the 88 survivors died in the first 6 months; 49 who have been followed up for up to 17 yr (median 10 yr) are still alive. The increased survival rate and relatively smooth course of most of the patients are concluded to be the result of a timely, aggressive surgical approach, with wide debridement and drainage, and the liberal use of supportive measures.

PANCREAS

Pancreatitis

8176 INVESTIGATION OF EXOCRINE PANCREATIC FUNCTION BY CONTINUOUS INFUSION OF CAERULEIN AND SECRETIN IN NORMAL SUBJECTS AND IN CHRONIC PANCREATITIS. (Eng.) Gullo, L.; Costa, P. L.; Fontana, G.; Labo, G. (Istituto di Clinica Medica e Gastroenterologia, Ospedale Sant'Orsola, I-40100 Bologna, Italy). *Digestion* 14(2):97-107; 1976.

The value of cerulein in the functional investigation of the exocrine pancreas was assessed in 24 controls and 29 patients with confirmed pancreatitis. The pancreas was stimulated by the i.v. infusion of cerulein (100 ng/kg/hr) and secretin (1 CU/kg/hr). The infusion was continued for 90 min to determine whether prolonged stimulation improves discrimination between normal and pathologic conditions. In controls, the mean volumes, bicarbonate outputs, lipase outputs, trypsin outputs, and chymotrypsin outputs were 46-76 ml/10 min, 4.16-8.03 mEq/10 min, 77,587-85,944 U/10 min, 765-947 U/10 min, and 7,927-10,190 U/10 min, resp. In the pancreatitis patients, values were 30-39 ml/10 min, 1.60-2.57 mEq/10 min, 15,132-27,193 U/10 min, 162-331 U/10 min, and 1,634-2,909 U/10 min, resp. In the case of volume, bicarbonate output, and lipase output in controls, the values increased throughout the experiment, and the values during the final 30 min were significantly greater than those during the initial 30 min ($p<0.001$). In the case of chymotrypsin ($p<0.001$) and trypsin ($p<0.05$), the values varied throughout the experimental period, but those during the final 30 min were significantly different from those in the initial 30 min. Unlike the controls, the patients with chronic pancreatitis demonstrated a progressive reduction in secretion during infusion. Outputs for the final 30-min period were significantly lower than those for the preceding period ($p<0.05$ for volume and bicarbonate; $p<0.005$ for lipase and trypsin; $p<0.001$ for chymotrypsin). The responses for the final 30-min period gave much clearer and more complete discrimination between normal and abnormal pancreatic function than did those from the preceding 30-min period.

8177 VIRAL ANTIBODY STUDIES IN PANCREATIC DISEASE. (Eng.) Capner, P.; Lendrum, R.; Jeffries, D. J.; Walker, G. (St. Mary's Hosp., London, England). *Gut* 16(11);866-870; 1975.

In an effort to determine a possible role of acute viral infection in the etiology of pancreatic disease, the sera of 54 patients with recent acute pancreatitis, 10 with recurrent pancreatitis, 7 with chronic pancreatitis, and 10 with pancreatic carcinoma were studied. The sera of 81 age- and sex-matched controls were also studied. Among the 29 patients with acute pancreatitis in whom paired sera were tested, 2 showed fourfold rises in antibody titers against herpes simplex, and 1 of these showed a fourfold rise against varicella zoster. No other significant increases in antibody titers were found. When the sera of the 54 patients were compared with those of the controls, there was a significantly greater incidence of antibodies to Coxsackie B_3 and B_4 viruses in the pancreatitis patients (59% and 59%, resp., versus 24% and 33%, resp.). The raised antibody titers against Coxsackie B viruses did not correlate in any way with the presence or absence of other nonviral factors associated with the pancreatitis. No evidence to support the suggestion that pancreatic disease is caused by acute viral infection has been found.

8178 NEW APPROACHES TO THE MANAGEMENT OF SEVERE ACUTE PANCREATITIS. (Eng.) Blackburn, G. L.; Williams, L. F.; Bistrian, B. R.; Stone, M. S.; Phillips, E.; Hirsch, E.; Clowes, G. H. A., Jr.; Gregg, J. (Boston City Hosp., 818 Harrison Ave., Boston, MA 02118). *Am. J. Surg.* 131(1):114-124; 1976.

Experience with 77 alcoholic patients with acute pancreatitis is presented. Thirteen patients had severe protracted acute pancreatitis. Two patients had fulminant pancreatitis, and two others had pancreatic abscesses. Nine of the patients did not fulfill the criteria usually used as a basis for surgical intervention. Specific preoperative diagnosis was obtained in these patients by the aggressive use of endoscopic cannulation of the pancreatic ducts, which documented the presence of surgically correctable lesions. These patients had sustained significant malnutrition, which was corrected by an average of 2 months of nutritional support. After proper preoperative identification of a specific lesion and correction of the malnutrition, the 11 patients without fulminant disease were operated on, with no deaths or significant complications. Nine of the patients had elective procedures, which included six distal pancreatectomies and one total pancreatectomy. Severe protracted acute pancreatitis can be identified, and once categorized, it can have therapeutic implications. Improved therapeutic results can be obtained by the more aggressive use of endoscopic cannulation of the pancreatic ducts and proper nutritional support.

8179 PANCREATIC EXCRETION OF 5,5-DIMETHYL-2,4-OXAZOLIDINEDIONE IN PATIENTS WITH CHRONIC PANCREATITIS. (Eng.) Noda, A.; Hayakawa, T.; Aoki, I.; Horiguchi, Y.; Toda, Y. (Second Dept. Internal Medicine, Nagoya Univ. Hosp., Sch. Medicine, 65, Tsuruma-cho, Showa-Ku, Nagoya City, Japan). *Am. J. Dig. Dis.* 20(11):1019-1026; 1975.

The abnormal pancreatic excretion of 5,5-dimethyl-2,4-oxazolidinedione (DMO) was studied in 44 patients with chronic pancreatitis (14 with calcification and 30 without calcification). Total DMO output 60 min after secretin stimulation (1 U/kg), when calculated as the output at a level of 10 mg/100 ml of plasma DMO, was linearly related to total volume and was significantly reduced (below 30 mg, $p<0.001$) in all but three patients. Over half the patients without calcification had a decreased DMO output with normal volume secretion, but 20/30 with calcification had a low DMO output with decreased volume flow. Data on DMO excretion 30 min after pancreozymin stimulation (1 U/kg, i.v.) were less efficient in finding abnormalities in these patients. A hypothesis was advanced that DMO diffusion into the pancreatic ducts might be primarily impaired in early chronic pancreatitis, and as the inflammation progressed to the final stage, DMO outflow from the ducts to the duodenum would be disturbed, with evolving diffusion impairment of the compound. The DMO in duodenal content, when expressed in terms of a maximal concentration ratio of duodenal juice/plasma, was significantly lower in chronic pancreatitis patients during the last 40 min after secretin stimulation. The present technique may be effective in diagnosing early chronic pancreatitis.

8180 DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS OF CHRONIC PANCREATITIS. (Ger.) Blum, A. L.; Bruhlmann, W.; Peter, R.; Krejs, G. J. (Medizinische Klinik und Institut fur Rontgen-Diagnostik, Stadtspital Triemli, CH-8063, Zurich, Switzerland). *Munch. Med. Wochenschr.* 117(50):1979-1986; 1975.

8205 FUNCTIONAL CONDITION OF THE KIDNEYS ACCORDING TO THE DATA OF RADIOISOTOPE INVESTIGATIONS IN CHRONIC DISEASES OF THE LIVER AND THE BILIARY TRACT. (Rus.) Loginov, A. S.; Khodarev, N. N.; Filatov, V. I. (Inst. of Gastroenterology, Moscow, USSR). *Ter. Arkh.* 47(10):81-91; 1975.

Renal function was investigated by radioisotope methods (determination of renal plasma flow and renography) in 16 control subjects, 44 patients with chronic hepatitis, in 52 patients with liver cirrhosis, and 22 patients with chronic cholecystitis. The nephrographic changes and the reduction of the renal plasma flow were most pronounced in decompensated liver cirrhosis, chronic active hepatitis, and in chronic hepatitis associated with chronic diseases of the bile ducts. There were no substantial changes in the renal function in compensated liver cirrhosis nor was there any correlation between the morphological type of the cirrhosis and the severity of the changes in renal function. Renal changes were least pronounced in patients with chronic cholecystitis and persistent hepatitis. Treatment for the main disease brought about improvement or total normalization of the renal function in the majority of the patients with chronic hepatitis and cholecystitis, while the renal disturbances were more persistent in cirrhosis, especially in decompensated forms. Insignificant disorders of the kidney structure and common hemodynamic disorders (mild dystrophy of the tubular epithelium, focal glomerulosclerosis, cortical ischemia, and activation of the juxtaglomerular circulation), found in 18 patients who died of hepatic insufficiency, cannot explain the major functional disturbances observed, suggesting that they were due to functional circulatory disorders.

8206 EVALUATION OF LIVER SCINTIGRAPHY WITH TUMORTRACER FOR DIFFERENTIATING FOCAL HEPATIC LESIONS. (Eng.) De Roo, M. J. K.; Kiebooms, L.; Drieskens, L. (Afdeling Nucleaire Geneeskunde, Gezwelziekten, A. Z. St. Rafael Katholieke Univ., Leuven, Belgium). *J. Belge Radiol.* 58(1):1-6; 1975.

The use of liver scintigraphy with tumor tracer (^{67}Ga citrate) in combination with colloid liver scintigraphy was evaluated in 42 patients. Among 30 patients with suspected liver metastases, the procedure resulted in three false-negatives and one false-positive. Among five patients with Hodgkin's disease or malignant lymphoma, this technique was negative in four cases; one was false-negative. There were five patients with nonmalignant liver lesions. Cold zones were found in multifocal cirrhosis (3 cases) and liver cysts (1 case). A subphrenic abscess showed a zone of intense hyperactivity. These results demonstrate that using digital treatment of the scintigraphic images with substraction of the colloid scan from the tumor scan, a better identification of focal liver disease is possible.

8207 CHANGES IN LIVER FUNCTION AFTER DIFFERENT TYPES OF SURGERY. (Eng.) Clarke, R. S. J.; Doggart, J. R.; Lavery, T. (Dept. Anaesthetics, Queen's Univ. Belfast, Belfast, N. Ireland). *Br. J. Anaesth.* 48(2):119-128; 1976.

Changes in liver function were determined in patients following intermittent i.v. anesthesia or after thiopentone-methoxyflurane-muscle relaxant anesthesia and different types of surgery. Both anesthetics lasted for 60-75 min. Twenty patients undergoing minimal surgery (cystoscopy, removal of a sebaceous cyst, or superficial biopsy) received 15.4 mg/kg of thiopentone, i.v., and 20 others received 0.19 μl/kg of althesin. Forty other patients undergoing body surface surgery (herniorrhaphy, ligation and stripping of varicose veins, or total mastectomy) received either thiopentone or althesin. Maintenance was with 75% nitrous oxide in oxygen. There were no significant adverse changes in the liver function tests over the first 4 days following surgery. There was a decrease in the serum bilirubin concentration to less than the control value on the 4th day after operation. Patients who underwent body surface operations had a significantly elevated serum bilirubin level at 24 hr after surgery, but this decreased by the 4th day. In the second series of experiments, four groups of 10 patients each who were undergoing minimal, body surface, gastric, or biliary tract surgery received thiopentone (5 mg/kg) followed by tubocurarine (0.5 mg/kg), 75% nitrous oxide in oxygen, and methoxyflurane (0.2%). In the patients who underwent minimal surgery, there were no significant changes in any of the liver function tests. After body surface surgery, the serum bilirubin level increased significantly over the first 24 hr, after which it decreased to less than the control value. The increase in bilirubin after gastric surgery was similar in magnitude to the other groups at 24 hr, but increased further during the next 3 days. After biliary tract surgery, there was a steady increase in bilirubin concentration from the end of surgery. This was significant at 6 hr, reaching a mean value of 1.26 mg/100 ml at 24 hr, and remaining increased at 96 hr. After gastric operations, LDH and SGOT were increased at 1, 6, and 24 hr, and these levels were normal by 96 hr. It is clear that the anesthetics used for patients undergoing minimal surgery have no deleterious effect on liver function. The changes in the serum concentrations of intracellular enzymes were probably not related to liver function.

8208 PREDICTION OF POSTOPERATIVE HEPATIC FAILURE IN MAJOR ABDOMINAL OPERATION: CLINICAL APPLICATION OF CYTOCHROME $a(+a_3)$ ASSAY OF LIVER SPECIMEN. (Eng.) Kamiyama, Y.; Ozawa, K.; Takeda, H.; Yamaoka, Y.; Takasan, H.; Honjo, I. (Kyoto Univ. Faculty Medicine, Kyoto, Japan). *Chir. Gastroenterol.* 9(4):523-527; 1975.

A rapid, simple method for the quantitative determination of cytochrome $a(+a_3)$ in homogenates of liver biopsy material was developed as an aid to the prediction of postoperative hepatic failure in critically ill patients or patients with liver cancer. Biopsy material, weighing 0.4-1.5 g, was obtained from liver edge at operation or autopsy in 234 patients, 60 of whom had liver cancer. If the cytochrome $a(+a_3)$ level was less than 0.5×10^{-10} M/mg mitochondrial protein, the rate of severe complications after abdominal surgery was 87%, regardless of whether a major or a minor operation was performed. Patients with a cytochrome a(+a_3) level over 0.5 x 10^{-10} M/mg mitochondrial protein in the liver remnant showed a good response to major hepatic resections, even when cirrhosis was present. Among 11 patients with resectable cancer and higher levels of cytochrome a(+a_3) who underwent abdominal surgery that varied in magnitude from local excision to right hepatectomy, 9 developed no postoperative complications; 1 of the remaining patients developed transient jaundice, and the other developed marked jaundice and ascites. The latter patient had a cytochrome a(+a_3) concentration of 0.5 x 10^{-10} M/mg protein. There were no significant differences in serum albumin, SGOT, total bilirubin, prothrombin time, and BSP retention in the patients with cytochrome a(+a_3) concentrations less than 0.5 x 10^{-10} M/mg and those with greater concentrations. It is concluded that assay of cytochrome a(+a_3) concentrations can help to elucidate the hepatic functional reserve and the ability of the liver remnant to survive major hepatic resection. The authors report that this determination has been done routinely prior to major surgery, and that if the results are less than half of the normal value, extensive operations should not be carried out.

8209 THE HEPATOTOXICITY OF PARENTERAL PROTEIN HYDROLYSATE-CONTAINING SOLUTIONS. (Eng.) Garnica, A. D. (Dept. Pediatrics, Univ. Florida, Gainesville, FL 32610). *Ann. Clin. Lab. Sci.* 6(5): 446-454; 1976.

The hepatotoxicity of protein hydrolysate-containing parenteral solutions was examined in 10 infants treated with a 20% glucose solution containing either 2.5% or 3.25% protein hydrolysate. Eight infants were hospitalized because of chronic diarrhea, and two because of prematurity and respiratory distress syndrome. Their gestational ages were 30-40 weeks, and their birth weights were 1,000-3,500 g. The patients received the protein hydrolysate infusion for 5 days to 14 weeks. SGOT and SGPT were measured before initiating parenteral nutrition and then at 7- to 14-day intervals during the infusion. The SGOT levels ranged between 21 and 78 U/ml before the infusion, the level being above 28 U in seven patients. The SGPT ranged between 4 and 43 U/ml, the level being above 21 U/ml in two cases. Serum transaminase elevations occurred during the infusions in eight infants, six of whom demonstrated subsequent decreases in the course of parenteral alimentation. Cholestasis, manifested by increased serum bilirubin (6 patients), leucine aminopeptidase (4 patients), or alkaline phosphatase (2 patients), occurred in six patients, but appeared to be related to gestational age, birth weight, or intercurrent complications; two patients had inflammatory ileal disease, one patient was premature, and one patient was premature and had sepsis. Serum amino acids were measured at least once in each patient 4-7 days after parenteral feeding was begun. The average levels of aspartic acid (0.91 mg/100 ml), glutamic acid (7.22 mg/100 ml), serine (4.95 mg/100 ml), glycine (7.62 mg/100 ml), and threonine (4.40 mg/100 ml) were elevated in all 10 patients. The alanine level was high in all but two patients, who were full-term and were 17 and 9 weeks old, resp., when treated. Liver biopsies from three patients showed minimal to moderate hepatic parenchymal disease with cholestasis. The data presently available do not unequivocally indict i.v. protein hydrolysate as a significant hepatotoxin in the concentrations currently used.

8210 PHARMACOLOGICAL ASPECTS OF (+)-CYANIDANOL-3. (Eng.) Bertelli, A. *In: New Trends in the Therapy of Liver Diseases. Proceedings of the International Symposium on New Trends in the Therapy of Liver Diseases*, Tirrenia, June 6-7, 1974. (New York: S. Karger): pp. 92-99; 1975.

Data on the biochemistry, toxicology, and pharmacology of (+)-cyanidanol-3 are reviewed, and the results of studies on the protective action of this drug on toxicity induced by CCl_4, ethionine, α-naphthylisothiocyanate (ANIT), and hyperbaric oxygen are presented. (+)-Cyanidanol-3 has a low toxicity, is well tolerated, and has no apparent teratogenic effect. The administration of 10% CCl_4 solution (1 cm^3/kg) to rats produced an increase in liver lipids from a mean control level of 18.9 mg/100 mg dry weight to 54.8 mg/100 mg. The p.o. administration of 200 mg/kg of (+)-cyanidanol-3 reduced this level to 36.5 mg/100 mg, and the administration of 400 mg/kg reduced the level to 29.3 mg/100 mg. The administration of ethionine produced an increase in liver lipids from a mean control level of 2.29/100 g to 9.60/100 g; the simultaneous administration of 100 or 200 mg/kg (+)-cyanidanol-3 reduced the liver lipid content to 6.40/100 g and 5.35/100 g, resp. The lipid infiltration, biliary proliferation, and fibroblastic proliferation induced by the administration of 250 mg/kg ANIT for 50 days were reduced by the simultaneous administration of (+)-cyanidanol-3 (200 mg/kg) for the same period. Hyperbaric oxygen intoxication in mice (3.5 atmospheres) produced convulsions and death in all cases. The administration of 50, 100, or 200 mg/kg of (+)-cyanidanol-3 prior to intoxication reduced the number of animals that experienced convulsions to 60, 20, and 40%, resp., and reduced the mortality rate to 60, 10, and 30%, resp. Hyperbaric oxygen intoxication also reduced the level of cerebral ATP to 38% and the hepatic succinodehydrogenase to 46%. Treatment with 50, 100, or 200 μg/kg of (+)-cyanidanol-3 increased the level of ATP to 75, 90, and 70%, resp., and the succinodehydrogenase level to 70, 75, and 70%, resp. Treatment with only 20 or 50 μg/kg of (+)-cyanidanol-3 for 7 days increased the ATP from a control level of 35% to 80 and 115%, resp. The succinodehydrogenase level was increased from a control level of 42% to 65 and 80% by 20 and 50 μg/kg (+)-cyanidanol-3, resp. (+)-Cyanidanol-3 acts both to normalize ATP levels and to inhibit functional and morphological damage manifested by the fatty infiltration of the liver. It also has a membrane stabilizing effect.

8211 MODELS OF LIVER DISEASES. (Eng.) McLean, A. E. M. *In: New Trends in the Therapy of Liver Diseases. Proceedings of the International*

Symposium on New Trends in the Therapy of Liver Diseases, Tirrenia, June 6-7, 1974. (New York: S. Karger):pp. 2-12; 1975.

Various models of liver disease are discussed. Cell injury, fatty liver development, changes in cell function during injury, repair of damaged cells, liver cell necrosis, liver cell regeneration, reorganization of liver structure after injury, and control of blood flow through the normal and diseased liver are discussed. Model systems that are relevent to acute liver injury include acute ethanol, CCl_4, ethionine, dimethylnitrosamine, paracetamol, CS_2, and galactosamine poisoning. The oldest and best model for liver cirrhosis is that produced by repeated inhalation of CCl_4. This method has been improved by the addition of phenobarbital treatment, resulting in a more rapid and certain production of cirrhosis. Cirrhosis may also be produced by repeated paracetamol poisoning, or with the long-standing severe fatty liver of choline deficiency. α-Naphthyl isothiocyanate and thioacetamide cause massive bile duct proliferation. The concept that has provided the most insight into the initial interaction between a chemical toxin and liver cells is that toxins are stable compounds that are activated into reactive molecules in the liver cell; the reactive molecules then attack cell macromolecules and destroy some cell function, leading to cell death or carcinogenesis. The modes of hepatotoxicity of paracetamol, CCl_4, and dimethylnitrosamine are discussed in relation to this concept.

8212 LIVER DISEASE ASSOCIATED WITH ALPHA$_1$-ANTITRYPSIN DEFICIENCY IN CHILDHOOD. (Eng.)

Moroz, S. P.; Cutz, E.; Cox, D. W.; Sass-Kortsak, A. (Hosp. Sick Children, 55 University Ave., Toronto, Ontario, M5G 1X8, Canada). *J. Pediatr.* 88(1):19-25; 1976.

The clinical, laboratory, and histologic data from 18 children presenting with liver disease in early life associated with α_1-antitrypsin (α-1-AT) deficiency and protease inhibitor ZZ (PiZZ), and from 7 apparently healthy PiZZ siblings are presented. In 12 of the 18 children with liver disease, the mean level of serum α-1-AT was 28% of normal. Fourteen children presented with the neonatal hepatitis syndrome, and there was hepatomegaly in three of the four remaining children. Four patients died of liver failure or the complications of severe chronic liver disease. Three patients are alive, but have severe liver disease and persistent abnormalities on all liver function tests. Eleven patients are relatively well, six having no clinical evidence of liver disease and five having hepatomegaly. Persistent elevation of SGOT during the 3rd yr of life and renal or pulmonary problems were associated with a poor prognosis. Among the seven siblings, one had previously unsuspected liver disease and three others had minimal evidence of liver involvement. The mean serum α-1-AT concentration in the PiZZ siblings was 22% of normal. The hepatic histology was studied in 21 of the 25 PiZZ children (4 siblings). The nine children who presented with the neonatal hepatitis syndrome in whom biopsy was carried out showed the histologic characteristics of giant cell hepatitis or hepatitis. Recent liver biopsy in two children who had the neonatal hepatitis syndrome and are now 13 and 19 yr of age showed only mild to moderate periportal fibrosis. Of the four patients with no history of jaundice, two had cirrhosis and two others had portal fibrosis, which was associated with hepatitis in one. The histology was normal in two of the four siblings tested, and portal fibrosis was observed in the other two. In all cases eosinophilic inclusions occurred in the cytoplasm of hepatocytes primarily in the periportal area. This study suggests that early hepatic involvement in children with α-1-AT deficiency does not necessarily imply a poor prognosis. Although no specific treatment is available, α-1-AT deficient, PiZZ children, along with the PiZZ siblings, should be identified and examined for evidence of liver disease.

8213 FINE STRUCTURAL OBSERVATIONS OF THE LIVER IN α-1-ANTITRYPSIN DEFICIENCY. (Eng.)

Yunis, E. J.; Agostini, R. M., Jr.; Glew, R. H. (Children's Hosp. Pittsburgh, 125 DeSoto St., Pittsburgh, PA 15213). *Am. J. Pathol.* 82(2):265-286; 1976.

The membrane sites involved in the storage of α-1-anti-trypsin (α-1-AT)-like material in the hepatocytes of patients with serum α-1-AT deficiency were investigated. Liver biopsies from three children with homozygous protease inhibitor ZZ (PiZZ) deficiency and varying degrees of liver pathology were examined by light and electron microscopy. Eighty percent of the hepatocytes of the three patients contained the α-1-AT-like deposits in varying degrees. These deposits primarily occurred within dilated, smooth endoplasmic reticulum (SER), but were also in the rough endoplasmic reticulum (RER), A 9-yr-old girl with severe liver cirrhosis had the greatest amount of intrahepatic α-1-AT. Five cytoplasmic sacs containing tubules resembling paramyxovirus nucleocapsid, adjacent to α-1-AT deposits in one area, were discovered. The second patient had multiple infections and α-1-AT levels that varied considerably, making a diagnosis difficult. The hepatocytes contained significantly fewer deposits than did those of the first patient. The third patient, who died at age 5.5 months, had hypoplastic intra- and extrahepatic bile ducts, bile stasis with portal fibrosis connecting portal areas, bile duct proliferation, and biliary cirrhosis. The number of deposits was intermediate between that in the other two patients. The frequent accumulation of the deposits in the SER suggested a possible mechanism explaining the abnormality in α-1-AT deficiency in the PiZZ genotype; the following model was proposed. *N*-acetylglucosaminyl-*N*-acetylglucosamine and mannose residues are attached to nascent and completed polypeptide chains primarily in the RER. Attachment of the same sugars to completed polypeptide chains may also occur in the SER to produce the linkage and core regions of one of the four proposed oligosaccharide moieties of M-type α-1-AT. Further addition of terminal region *N*-acetylglucosamine, galactose, and sialic acid residues occurs in the Golgi apparatus. The linkage between the oligosaccharide moieties and the polypeptide hain involve asparagine residues. In the case of -type α-1-AT, one of the linkage region asparagine esidues has been replaced by some other amino acid, hereby preventing the attachment of one oligosac- haride side chain; this α-1-AT would thus accumu- ate in the smooth membranes.

214 NUCLEAR MEDICINE INVESTIGATIONS ON THE GENESIS OF ANEMIA IN CHRONIC LIVER DISEA- ES.

(Ger.) Konrad, H.; Kiencke, H.; Krueger, M.; owotny, P.; Koch, K. (Klinik fur Innere Medizin, ereich Medizin, Universitat Rostock, Rostock, E. ermany). *Radiol. Diagn. (Berl.)* 17(1):140; 1976.

ertain variables involved in the pathogenesis of nemia in chronic liver disease were examined. Vi- amin B_{12} resorption was studied in 175 cases, iron inetics in 60, RBC survival time and plasma volume n 100, quantitative excretion of fecal blood in 10, nd intestinal hemorrhage localization in 8. The verage B_{12} resorption was reduced in all patient roups, significantly in 18%. In the iron kinetics tudy, plasma iron and RBC iron turnover was elevated n 26 of the 60 patients, all of whom were anemic r had increased marrow erythropoiesis. Iron uti- ization was generally unchanged. RBC half-life as lower in all patient groups, which was implica- ed causally in 34 of the 100 patients in the RBC tudy group. In 12 cirrhotic cases, the spleen howed marked erythrocytoclasis. Plasma volume was aised only in cirrhosis; four cirrhotic patients ad dilution anemia.

215 COINCIDENCE OF HODGKIN'S DISEASE AND EPITHELOID-CELL GRANULOMAS IN LIVER AND PLEEN.

(Ger.) Stolzenbach, G.; Garbrecht, M.; ertelsmann, R.; Kastendieck, H. (II. Medizinische niversitatsklinik, 2000 Hamburg 20, Martinistr. 52, . Germany). *Dtsch. Med. Wochenschr.* 101(18):709- 11; 1976.

wo case histories of extensive epitheloid-cell ranulomas in patients with Hodgkin's disease (HD) re reported. A 34-yr-old woman had been under adiotherapeutic management of lymphocyte-rich HD or 10 yr, at which time a recurrence of cervical ode enlargement prompted a diagnosis of HD IIIA. massive conglomerate tumor was established lympho- raphically at the level of L1-L3. There were no ther significant signs or symptoms. An extensive pitheloid-cell granuloma was unexpectedly found fter splenectomy and liver biopsy without evidence f HD involvement. Bacteriology and serology were egative. Subsequent liver biopsy found only slight eactive hepatitis. The second patient, a 33-yr-old oman, presented with mixed HD, with moderate trans- minase elevation, cervical node enlargement, and light splenomegaly without pathological signs. aparotomy 3 months postradiation revealed splenic nd hepatic infiltration by epitheloid-cell granu- oma without signs of HD. Subsequent hepatomegaly as reduced with prednisone. The patient is being aintained under long-term radiation and prednisone anagement of para-iliac, para-aortic, and inquinal ode enlargement following exacerbation of lympho- yte poor HD. Epitheloid-cell granuloma is interpreted as a morphological expression of T-cell dysfunction.

8216 THE LIPID-CHEMICAL FEATURES OF THE BIOPSIED HUMAN LIVER TISSUES OF PATIENTS WITH MALIGNANT NEOPLASTIC DISEASES.

(Eng.) Nakazawa, I.; Yamagata, S.; Miura, K. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 118(Suppl.): 149-158; 1976.

Lipid and chemical changes were studied in liver biopsy specimens from 57 patients with various types of malignant neoplastic diseases, 45 patients with benign hepatic diseases, 25 patients with benign diseases not involving the liver, and 6 patients with malignant disease in combination with benign hepatic disease. In the patients with benign hepatic diseases (cirrhosis and hepatitis), the mean percentages of the fatty acids $C_{16:1}$, $C_{18:1}$, and $C_{14:0}$ (6.5%, 21.9%, and 1.43%, resp.) were increased in comparison to those in 22 controls (4.6%, 18.8%, and 1.04%, resp.), and the mean percentages of $C_{18:0}$, $C_{20:4}$, $C_{22:6}$, and $C_{18:2}$ (11.2%, 6.1%, 7.4%, and 14.0%, resp.) were decreased in comparison with controls (13.7%, 7.0%, 8.9%, and 16.7%, resp.). The most significant difference between the lipid pattern in the patients with benign or malignant disease was the ratio of fatty acid content of the phospholipid fraction to that of triglyceride; these ratios were greater than 2.20 in 40 of 47 patients with malignant neoplasms and in 3 of 4 patients with both malignant and benign disease, but were under 2.19 in 35 patients with benign disease. Four patients with early gastric cancer and one patient with early pancreatic cancer had ratios greater than 3.00. The calculation of this ratio may be useful in the diagnosis of malignant disease.

8217 STUDIES IN CHOLESTASIS OF PREGNANCY. V. GALLBLADDER DISEASE, LIVER FUNCTION TESTS, SERUM LIPIDS AND FATTY ACID COMPOSITION OF SERUM LECITHIN IN THE NON-PREGNANT STATE.

(Eng.) Samsioe, G.; Svendsen, P.; Johnson, P.; Gustafson, A. (Sahlgren's Hosp., S-413 45 Gothenburg, Sweden). *Acta Obstet Gynecol. Scand.* 54(5):417-423; 1975.

The prelavence of cholecystopathia was studied in 11 women who had pruritus gravidum and 12 women who had hepatosis of pregnancy during a preceding pregnancy. The liver function tests, serum lipids and lipoproteins, and the relative fatty acid composition of serum lecithin were also examined. The incidence of gallbladder disease, evaluated by cholecystography, was 23.7%. Among the women with previous cholestasis of pregnancy and a positive x-ray, no characteristic changes in liver function tests or serum lipids were observed. The women with a positive x-ray had a lower α-lipoprotein cholesterol than women with a negative x-ray. A characteristic finding among women with a positive x-ray was a lower relative content of palmitic acid in the serum lecithin than that found in 18 normal control women (16:0). The low palmitic acid content may suggest an influence on liver lecithin synthesis pathways, and the serum lecithin fatty acid composition may reflect similar changes in bile lecithin. The basic defect in cholecystopathia influencing liver lecithin synthesis might be the primary cause for disturbed cholesterol solubility in bile and of the frequent occurrence of gallstones in cholecystopathia of pregnancy.

8218 HEPATOMEGALY. (Eng.) Kaude, J. V.; DeLand, F. (Dept. Radiology, Box 730, Univ. Florida Coll. Medicine, Gainesville, FL 32610). *Med. Clin. North Am.* 59(1):145-167; 1975.

The radiologic diagnostic procedures in clinical use for the evaluation of hepatomegaly are reviewed. Plain roentgenograms of the abdomen are useful in identifying opacities and in determining subsequent diagnostic study. Other noncontrast studies include tomography or zonography (cut films) and chest films with or without fluoroscopy. Barium studies of the gastrointestinal tract are the best procedures for identifying a primary neoplasm or varices. For contrast studies in jaundiced patients and in those with abnormal liver function, i.v. cholangiography should be used rather than oral cholangiography, which has no value here. Two special procedures, in which contrast medium is injected directly into bile ducts, are transduodenal pancreatocholangiography and percutaneous transhepatic cholangiography. In patients with obstructive jaundice, the two combined procedures demonstrate not only the nature and extent of the disease, but also the exact site of the obstruction. Operative cholangiography can reduce the incidence of overlooked common or hepatic duct stones. Selective hepatic arteriography offers the greatest specificity of all current procedures for the investigation of liver masses. Pharmacoangiography (using bradykinin and tolazoline) has largely replaced splenoportography in investigating the portal venous system, even in determining portal hypertension. Scintigraphy and ultrasonic scanning are straightforward screening procedures usually devoid of risk. In patients with known primary malignancies, the demonstration of a hepatic mass by these procedures markedly increases the probability of a metastatic lesion, but a negative scan does not rule out the possibility of metastases, especially lesions less than 2-3 cm in diameter. Scanning is preferred in investigating parenchymatous hepatic disease and is usually satisfactory in following the results of a given treatment or after hepatic surgery.

8219 FATTY HEPATOSIS IN CHILDREN. (Rus.) Malakhovsky, Yu. E.; Likhachev, A. A.; Galin, A. A.; Mordovkin, V. B. (Kemerovo Oblast Clinical Hosp., Kemerovo, USSR). *Vopr. Okhr. Materin. Det.* 20(9):50-57; 1975.

Symptomatological, diagnostic, and etiological aspects of fatty degeneration of the liver in 29 children (aged 7 months to 12 yr) are described. The disease was diagnosed against the background of toxic pneumonia in nine cases, systemic lupus erythematosus in two, active rheumatism in two, and periarteritis nodosa and peptic ulcer of the duodenum in one each. The anamnestic investigation revealed intestinal infections with *Escherichia coli* in five patients, dysentery in two, viral hepatitis in three, giardiasis of the bile ducts in two, and hemorrhagic vasculitis in one. In many children, such diseases were associated with frequent respiratory infections (8 cases), unbalanced diet (12), repeated pneumonia (4), rickets (6), iron deficiency anemia (8), and antibiotic and hormone therapy in the past (16). In 20 cases, the clinical picture was of the "forme fruste" type. Another nine displayed symptoms characteristic of active hepatitis, and fatty liver degeneration terminated in hepatic coma in these patients. Biochemical tests revealed hypercholesterolemia in 10 patients, hyper-betalipidemia in 7, moderate hypoproteinemia with hypergammaglobulinemia in 7, high blood transaminase levels in 4, and hypoglycemia in 5. Pathomorphological examinations showed fatty degeneration of the hepatocytes in 15 cases, and large-cell fatty infiltration in 5.

8220 INVESTIGATION OF THE ABNORMAL LOW-DENSITY LIPOPROTEINS OCCURRING IN PATIENTS WITH OBSTRUCTIVE JAUNDICE. (Eng.) Kostner, G. M.; Laggner, P.; Prexl, H. J.; Holasek, A.; Ingolic, E.; Geymayer, W. (Inst. Medical Biochemistry, Univ. Graz, A-8010 Graz, Austria). *Biochem J.* 157(2):401-407; 1976.

The abnormal lipoproteins of the density range 1.019-1.063 g/cm^3 occurring in the plasma of patients with obstructive jaundice were studied. Subfractionation of this density class by combined sodium phosphotungstate precipitation, ultracentrifugation, and column chromatography on hydroxyapatite and agarose gel yielded essentially three fractions: lipoprotein-X; a triglyceride-rich lipoprotein ("lipoprotein-Y"); and an abnormal lipoprotein, lipoprotein-B. The electron microscopic appearance, hydrated densities, chemical composition, and immunochemical characteristics were markedly different. Electron microscopy revealed that lipoprotein-X had a characteristic disc-like structure, with a long axis of 50 nm and a short one of 9 nm, forming stacks. Lipoprotein-Y was composed of relatively uniform spherical particles, and stacked discs were seen only infrequently. Lipoprotein B exhibited spherical particles that were smaller than those of lipoprotein-Y. The protein moiety of lipoprotein-X consisted primarily of apolipoprotein-C and albumin. Lipoprotein-Y showed, in addition to apolipoprotein-C, the presence of apolipoprotein-B. The lipoprotein-B fraction isolated from sera of these patients had higher triglyceride and free cholesterol contents than that of normal individuals and an unusually high content of apolipoprotein-C. The relative distribution of lipoprotein-X, lipoprotein-Y, and lipoprotein-B varied from patient to patient. The importance of considering the existence of lipoprotein-Y in screening patients for cholestasis by the lipoprotein-X test is discussed.

8221 PORPHYRIA VARIEGATA. (Ger.) Hofmann, C.; Schmidt, D.; Braun-Falco, O. (Medizinische Klinik der Universitat Munchen, Munich, W. Germany). *Munch. Med. Wochenschr.* 117(50):1969-1974; 1975.

The case history of a 34-yr-old woman with porphyria variegata (PV) is described. The personal history was clinically unexceptional except for occasional eczema; the family history included paternal urticarial facial erythema on exposure to light, with a coproporphyrinuria of 244 µg/24 hr. One female offspring of the patient presented with a neurodermitis diffusa. Since pregnancy, the patient had shown increasing light-sensitivity, with erythematous involvement of both hands, lower arms, calf, and lips. In the 24-hr urine sample, the delta-aminolevulinic acid level was 5,460-9,300 µg (normal 2,392); porphobilinogen, 6,300-13,230 µg (normal 846); uroporphyrin, 40-240 µg (normal 13.6); and coproporphyrin, 1,012-1,159 µg (normal 81). The fecal levels in µg/g included uroporphyrin, 37 (normal o-trace); coproporphyrin, 393 (normal 15); and protoporphyrin, 777 (normal 24). The RBC levels in µg/100 ml were uroporphyrin, 0.4 (normal 0.99); coproporphyrin, 0.8 (normal 0.3); and protoporphyrin, 29.4 (normal 26). The high fecal excretion of proto- and coproporphyrins is differentially diagnostic of PV relative to porphyria cutanea tarda and acute intermittent porphyria. Liver biopsy was unremarkable except for slightly elevated lipopigment. All other paraclinical data were normal or borderline normal. Transmission is believed to be autosomal dominant; it is not sex-linked. Therapy consisted of protein-rich diets, supplemented by various commercial preparations.

8222 REYE SYNDROME: RESULTS OF INTENSIVE SUPPORTIVE CARE. (Eng.) DeVivo, D. C.; Keating, J. P.; Haymond, M. W. (St. Louis Children's Hosp., 500 South Kingshighway, St. Louis, MO 63110). *J. Pediatr.* 87(6):875-880; 1975.

The management and pathophysiology of 36 children (aged 5 months-15 yr) with Reye's syndrome who were hospitalized from January 1966 through June 1975 are described. Ten patients died; 7 of these deaths occurred in the 11 patients admitted between 1966 and 1971. These 11 patients were managed by various methods, without a consistent plan. The 25 patients admitted between 1972 and 1975 were staged into four groups and given a uniform pattern of care. This included: for the five stage I patients, a daily infusion of 1,600 ml/m^2 of 5-10% glucose-Isolyte M; for the 20 stage II or III patients, a continuous infusion of hypertonic glucose solution containing 300 g glucose, 40 mEq NaCl, and 30 mEq potassium acetate (14 patients) or potassium phosphate (6 patients). Twelve of the 20 were also treated with hypertonic mannitol (102 g/kg, i.v.) for 45-60 min and were electively intubated shortly after admission. These 20 patients were also given ampicillin and vitamin K (1 mg, i.v., or 5 mg, i.m.), and blood pressure, arterial gases, and various chemicals in the blood were monitored. All 19 stages I-II patients and 3 of 6 stage III patients survived. Sustained hyperglycemia in the range of 250-300 mg/dl was present during the first 60 hr of treatment, and a mixed acid-base disturbance was observed in all patients during the first 24 hr. The amount of glucose retained was 620 mg/kg/hr during the first 24 hr, and 567 mg/kg/hr during the second 24 hr. Serum calcium concentrations remained either in the normal range or slightly decreased (7.0-7.5 mg/dl). It is concluded that the reduction in the case fatality rate is due to early diagnosis, recognition of milder cases, and intensive medical support.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

8243 THE STATUS OF PHOTOTHERAPY IN THE PREVENTION AND TREATMENT OF NEONATAL JAUNDICE. (Ger.) Margies, D.; Jahrig, K. (Kinderklinik, Ernst-Moritz-Arndt-Universitat, Greifswald, E. Germany). *Kinderaerztl. Prax.* 43(1):19-27; 1975.

Experiences with various modalities in the management of neonatal jaundice were critically compared. The absorption spectra of 14 different sera of icteric newborns was assayed spectrophotometrically, and the bilirubin concentration was assayed by direct photometry, radiated by blue light, and unradiated. Whole body posterior and anterior exposures were also applied to 50 premature neonates (1,260-2,500 g), 3-10 days of age, in 12 12-hourly photoperiods. *In vitro*, the bilirubin depression after a 6-hr exposure was 51.5% of initial levels, falling to extinction in another 6 hr. *In vivo*, the bilirubin decrease was 31.1% of initial values; the average pre- and postradiation serum levels were 14.11 and 9.74 mg/100 ml, resp. Birth weight, nutrition, general condition, and degree of hyperbilirubinemia had no significant effect on the result. Higher initial bilirubin levels and age at therapy reduced the photoeffect. Severe side-effects were not found. Comparatively, enzyme induction by phenobarbital and nikethamide elicited significant decreases in bilirubin, supplemented by replacement transfusion in refractory cases. Transfusion alone was least effective with premature infants, while enzyme induction alone or combined with blue light exposure was most effective in dysmature (small for gestation age) infants. Blue light therapy alone was somewhat less effective with pre- than dysmature cases. None of the methods significantly affected the RBC picture. The reduction in the number of infants with hyperbilirubinemia after blue light therapy establishes it as a valuable complementary method in icterus management.

8244 CIRCANNUAL VARIATION IN HYPERBILIRUBINEMIA OF NEONATES. (Eng.) Carletti, B.; Kehyayan, E.; Montalbetti, N.; Dansi, A.; Halberg, F.; Vaitkus, E.; Anderson, J. A.; Scheving, L. E.; Kanabrocki, E. L. (Ospedale Regina Elena, Milan, Italy). *Chronobiologia* 2(4):346-354; 1975.

Studies were carried out in the United States and in Italy to determine if there is a circadian rhythm in hyperbilirubinemia of neonates. The study covered all infants born in one hospital in Milan between January, 1970 and April, 1972 and in one hospital in Minneapolis between 1959 and 1966. The percentage of newborns with jaundice (serum bilirubin $\geq$ 10 mg%), the monthly mean maximal blood bilirubin value at any time after birth in icteric neonates, and the monthly mean of icterus length were determined in both studies. The frequency of jaundice sharply increased during the winter months in the infants born in Milan. No such rhythm occurred in the infants born in Minneapolis. Whether the findings of a circadian rhythm in the infants born in Milan is related to a reduced exposure to natural light during the winter, as compared to the rest of the year, remains to be investigated.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

8247 THE DIAGNOSTIC SIGNIFICANCE OF LIVER CELL INHOMOGENEITY: SERUM ENZYMES IN PATIENTS WITH CENTRAL LIVER NECROSIS AND THE DISTRIBUTION OF GLUTAMATE DEHYDROGENASE IN NORMAL HUMAN LIVER. (Eng.) Guder, W. G.; Habicht, A.; Kleissl, J.; Schmidt, U.; Wieland, O. H. (Klinisch-chemisches Institut, Stadt. Krankenhaus Munchen-Schwabing, D-8000 Munchen 40, Kolner Platz 1, W. Germany). *Z. Klin. Chem. Klin. Biochem.* 13(7):311-318; 1975.

The significance of markedly increased glutamate dehydrogenase activity in the sera of 16 patients with acute right-sided cardiac failure associated with high central venous pressure was investigated. The distribution of glutamate dehydrogenase was also studied in microdissected tissue samples from four patients with normal livers. The activity of glutamate dehydrogenase exceeded 1,000 U/l in the sera of over half of the 16 patients. Hepatomegaly occurred in almost all of the 16 patients. Seven patients died, and histological examination of the liver confirmed that various degrees of central liver necrosis were present in all cases. Among the 16 patients, the alanine and aminotransferase and aspartate aminotransferase activities were increased 5- to 200-fold over the normal upper limits. The absence of jaundice and the presence of normal alkaline phosphatase levels indicated that cholestasis was not present in the 16 patients. The aminotransferase activities in a group of 15 patients with acute viral hepatitis were not significantly different from those of the 16 patients; however, the ratio of alanine aminotransferase to glutamate dehydrogenase differed by a factor of 40, ranging from 0.25 to 2.2 in the patients with cardiac failure and from 15 to 138 in the patients with hepatitis. In the four microdissected normal livers, a 1.7-fold higher glutamate dehydrogenase activity was found in the central part of the liver lobule than in the peripheral portion. This higher activity could explain the relatively higher serum glutamate dehydrogenase activities found in liver diseases involving central necrosis. Glutamate dehydrogenase determinations in serum, in combination with alanine aminotransferase determinations, may be valuable in defining the degree and intralobular distribution of liver cell necrosis.

8248 HISTOPATHOLOGICAL CHANGES IN THE LIVER FOLLOWING A PARACETAMOL OVERDOSE: CORRELATION WITH CLINICAL AND BIOCHEMICAL PARAMETERS.

(Eng.) Portmann, B.; Talbot, I. C.; Day, D. W.; Davidson, A. R.; Murray-Lyon, I. M.; Williams, R. (King's Coll. Hosp. Medical Sch., London S.E.5, England). *J. Pathol.* 117(3):169-181; 1975.

The histological changes in the liver after paracetamol overdose were assessed in 104 patients, and a morphometric technique was used to determine the severity of hepatocyte loss and its relation to survival and to changes in various biochemical parameters. Thirty-eight patients developed fulminant hepatic failure. Confluent centrilobular necrosis was the most striking change seen in the liver biopsies taken up to 6 days after the paracetamol overdose. When biopsies were not taken until after 6 days, necrosis was less evident; liver cells had been largely removed, and with their disappearance, collapse of the reticulin framework occurred in the affected areas. A mild inflammatory reaction was replaced by a dense accumulation of pigmented macrophages in the area of cell loss. Fatty microvacuoles were found in surviving liver cells, and their presence seemed to parallel regenerative activity. Apparent bile ductule reduplication with great pleomorphism of component cells was a relatively late development, and it was only seen in biopsies showing extensive necrosis (grades II and III). Cholestasis was usually evident in the areas of surviving parenchyma in the more seriously affected cases. These changes corresponded in time to the appearance of deep cholestatic jaundice, which often lasted 4-8 weeks before gradual recovery ensued. Liver function tests eventually became completely normal. Seventy-seven patients survived the overdose, and only 1 of the 17 survivors whose initial biopsy showed the pattern of interlobular bridging necrosis had appreciable residual fibrosis in a follow-up biopsy taken after 1 yr. A quantitative estimate was made of the amount of surviving liver parenchyma; the hepatocyte volume fraction (HVF) in 76 biopsies performed within 10 days of the overdose correlated well with the clinical course and both with the maximal prolongation of the prothrombin time and the peak plasma bilirubin concentration in the first 10 days. An HVF value (normal 85%) of less than 40% was found only in patients who died. However, HVF measurements on biopsies from three survivors taken later than 10 days after the overdose showed that survival was possible below this critical level.

8249 HALOTHANE HEPATITIS WITH RENAL FAILURE TREATED WITH HEMODIALYSIS AND EXCHANGE TRANSFUSION.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

8253 EFFECTS OF (+)-CYANIDANOL-3, A NEW FLAVONOID, IN ACUTE VIRAL HEPATITIS.

(Eng.) Borel, G. A.; Schelling, J. L.; Magnenat, P. *In: New Trends in the Therapy of Liver Diseases. Proceedings of the International Symposium on New Trends in the Therapy of Liver Diseases, Tirrenia, June 6-7, 1974.* (New York: S. Karger): pp. 170-176; 1975.

A double-blind controlled study of the effects of (+)-cyanidanol-3 in patients with acute viral hepatitis was made. Of 28 patients, 14 received the drug (1 g/day p.o. for 2 days; 2 g/day for 23 days) and 14 received a placebo. In a second study, 15 patients received only 1 g/day. No side-effects were noted. There were no differences in clinical symptoms or evolution between treated patients and

ntrols. Total serum bilirubin levels before and
ter 2 weeks of treatment were similar. However,
e $T_{1/2}$ for hyperbilirubinemia was 3.2 days in
eated patients and 4.9 days in untreated patients,
significant difference ($p<0.05$). Other liver
nction tests were similar. Patients treated with
g/day did not differ from placebo patients; there-
re this drug may only be effective at >1 g/day.

54 INDUCTIVE EFFECT OF PHENOBARBITAL IN THE TREATMENT OF PATIENTS WITH RESIDUAL PHE- MENA OF VIRAL HEPATITIS.

(Rus.) Oleinik, A. N.;
akun, N. P.; Bogachik, L. I.; Andreichin, M. A.
ernopol Medical Inst., Ternopol, USSR). *Vrach.*
lo (1):139-141; 1976.

e inductive effect of phenobarbital was studied in
animal experiment and in a clinical trial on nine
tients with residual viral hepatitis 2-6 months
ter the onset of the disease. Phenobarbital, ad-
nistered to albino male rats in daily doses of
30 mg/kg, caused considerable increases in bile
cretion and in the total quantity of bile; sti-
lated the synthesis of primary bile acids; their
njugation with amino acids; and the synthesis, con-
gation and secretion of bilirubin, without affect-
g erythrocytes. Phenobarbital had no effect on
olesterol excretion. In the clinical trials, the
tients received 0.03 mg/kg phenobarbital three
mes daily, p.o., for 10 days. General improve-
nt of well-being was noted after 2-4 days. Phe-
barbital caused favorable clinical-biochemical
anges (reduced bilirubinemia, relief of pain,
sappearance of anorexia and icteric sclera, and
rmalization of the size of the liver). The effect
phenobarbital in patients with residual symptoms
viral hepatitis is ascribed to its inductive
fect on uridinediphosphate glucuronyl transferase
l other liver enzymes.

55 THERAPY WITH CORTICOSTEROIDS IN VIRAL HEPATITIS.

(Rus.) Staroselsky, D. V.
tai Medical Inst., USSR). *Klin. Med.* 54(2):66-
1976.

rrent views on and experience with corticosteriod
erapy for acute viral hepatitis are presented.
rticosteriod therapy is indicated only for very
vere forms of viral hepatitis, exacerbations, re-
pses, and for cases showing development to chro-
form. The therapy should be initiated at an
rly stage, because even very high doses are inef-
tive at advanced stages with pronounced dystrop-
and necrotic processes in the liver. Cortico-
eroids do not reduce the time necessary for the
al normalization of the bilirubinemia. While
l administration is most efficient, it can be
plied through the umbilical vein if oral adminis-
ation is impossible. Liver necrosis may require
renteral administration. The doses should be mo-
ate (30-35 mg/day, three times daily, after
ls for prednisolone), because larger doses are
ineffective as smaller ones. The duration of
therapy averages 3 weeks, with the daily dose
ng reduced after the first 4-5 days. The course
of therapy is somewhat shorter when using dexamethasone or triamcinolone. Cases showing signs of development to chronic hepatitis may require a therapy course of 1.5-2 months with daily doses of 20-25 mg.

8256 EFFECT OF A SHORT COURSE OF HORMONE THERAPY ON VIRAL HEPATITIS.

(Rus.) Duka, T. V.; Zeigermakher, G. A.; Zhivitsa, L. V.; Komarova, E. M. (Zaporozhye Inst. Postgraduate Training Physicians, Zaporozhye, USSR). *Klin. Med.* 54(2): 70-74; 1976.

Therapeutic results obtained with short-term (5-7 days) and long-term (2-4 weeks) glucocorticoid (prednisolone) therapy in 55 children aged 1-14 yr and 80 adults aged 17-65 yr with viral hepatitis with pronounced intoxication are reported. Seventy-three patients (30 children, 43 adults) received short-term prednisolone therapy (28 mg/day, total dose 127.3 mg in children; 33-50 mg/day, total dose 165 mg in adults). Sixty-two patients (25 children, 37 adults) received long-term prednisolone therapy with decreasing doses (total 250.6 mg for children, 542.5 mg for adults). The time required for the normalization of the clinical and biochemical parameters (color of skin and sclera, bilirubinemia, size of the liver, thymol test) and the length of the hospitalization were about the same in most patients under short- and long-term therapy, while the serum bilirubin level normalized and jaundice disappeared in a significantly shorter time under short-term therapy. Side-effects (furunculosis, intestinal hemorrhage, and steroid diabetes) occurred in six cases under long-term therapy, while no side-effects were observed under short-term therapy. The findings indicate that long-term glucocorticosteroid therapy has no advantage over short-term therapy, and that short-term therapy is also applicable in cases of relative contraindications (peptic ulcer, hypertension, diabetes mellitus, prepuberty, advanced age, adipositas). Long-term therapy is indicated only for young children and cases of therapy failure of the short-term therapy.

8257 RECENT ADVANCES IN THE STUDY OF THE EPIDEMIOLOGY OF HEPATITIS B.

(Eng.) Szmuness, W. (New York Blood Center, 310 East 67th St., New York, NY 10021). *Am. J. Pathol.* 81(3):629-650; 1975.

Published and unpublished large-scale population studies of hepatitis B are reviewed. The spectrum of host responses following exposure is unusually wide. Hepatitis B appears to be one of the most widespread infections; the total number of chronic carriers of the hepatitis B antigen has been estimated as at least 120 million. The following factors have been found to be closely associated with the risk of hepatitis B: geography, sex, age at testing, age at primary infection, socioeconomic status, ethnicity, occupation, sharing a household with a carrier, sexual promiscuity, and immunologic responsiveness. Data concerning the infectivity of an asymptomatic carrier are ambiguous; whether a carrier can transmit the virus by sexual intercourse also remains unknown.

Available evidence suggests that genetic factors may be important in the aggregation and segregation of hepatitis B.

8258 VIRAL HEPATITIS IN CHILDREN. (Eng.) Rao, V. S.; Reddi, Y. R.; Rohini, K. (Inst. Child Health, Niloufer Hosp., Hyderabad, India). *Indian Pediatr.* 12(8):659-663; 1975.

The results of therapy with Liv. 52 in 120 pediatric patients with viral hepatitis are presented. Liver biopsies were carried out on admission and repeated during and after treatment at intervals varying from 3 to 12 weeks. The patients were placed into one of four treatment groups of 30: group A received Liv. 52 alone (2 teaspoons, 2 or 3 times daily or 2 tablets, 3 times daily); group B received prednisone alone (2 mg/kg for 2 weeks or 0.5-1 mg/kg for 1 week); group C received both Liv. 52 and prednisone; and group D received a placebo. The clinical, biochemical, and histopathologic recovery was earliest in group A. Jaundice disappeared clinically in a mean period of 12 days in group A, while in groups B, C, and D, the mean period was 17, 11, and 14 days, resp. The levels of serum bilirubin, thymol turbidity, transaminases, and alkaline phosphatase returned to normal in 10, 14, 18, and 16 days, resp., in group A; 18, 21, 26, and 23 days, resp., in group B; 12, 13, 21, and 16 days, resp., in group C; and 26, 30, 34, and 30 days, resp., in group D. Histopathologic recovery, in terms of complete regeneration of liver cells, decrease or disappearance of mononuclear infiltration of portal tracts, absence of vacuolation of hepatocytes and normalization of their glycogen content, occurred within 5 weeks in groups A and C; histopathologic recovery occurred in 10 and 14 weeks, resp., in groups B and D. Liv. 52 is a herbal preparation with anabolic, aperient, diuretic, stomachic, and protective effects; it also has a regenerative action on the liver. Because it is inexpensive and has no toxic side-effects, it is safe for the management of viral hepatitis.

8259 THE SIGNIFICANCE OF HB ANTIGENEMY IN APPARENTLY HEALTHY PERSONS IN THE CLINIC FOR LIVER DISEASES. (Eng.) Lesnicar, J.; Zaversnik, H.; Ferluga, D.; Kirk, C. (Hosp. Infectious Diseases, Celje Town Hosp., 63000 Celje, Yugoslavia). *Acta Hepatogastroenterol.* 22(5):297-304; 1975.

The significance of hepatitis B antigenemia was evaluated in 71 apparently healthy antigen carriers and in 120 patients who had recovered from type B hepatitis. Histologic examination of liver tissue obtained at biopsy in the 71 apparently healthy carriers revealed hepatitis persistens focalis in 41, hepatitis persistens diffusa in 15, chronic aggressive hepatitis in 3, cirrhosis in 1, acute hepatitis in 3, and normal liver or other changes in 8. None of these subjects had clinical symptoms of hepatitis. All 71 patients denied that they had had any type of hepatitis. Among the 120 patients who recovered from hepatitis, only 5% remained permanent hepatitis B antigen carriers. The results indicate that liver biopsies and follow-up examinations should be carried out in patients with hepatitis B antigenemia.

8260 CLINICAL COURSE AND PROGNOSIS OF ACUTE HEPATITIS. (Eng.) Nielsen, J. O. (Bispebjerg Hosp., Copenhagen 2400 NV, Denmark). *Ann. Cli Res.* 8(3):151-157; 1976.

Information on the clinical course and prognosis of acute viral hepatitis is reviewed with respect to t development of fulminant hepatitis and chronic live diseases. The clinical course of acute viral hepatitis varies from asymptomatic to fulminant, and th final outcome can be complete recovery, chronic hepatitis, or cirrhosis. Fulminant hepatitis appears infrequently (1-2% of patients with clinical hepatitis) in both type A and type B infections. Nearl 10% of patients with acute viral hepatitis type B (HB) develop either chronic hepatitis or cirrhosis. The exact figures for progression to chronicity in patients with type A infections are probably less, but are still not fully known. During the acute phase of the disease, the patients with later progression to chronicity differ significantly from those with subsequent resolution in a number of serological, biochemical, and morphological variables. Persistence of HB surface antigenemia for more than 13 weeks, a high concentration of circulating Dane particles, and the presence in the serum of the "e" antigenic determinant are reliable prognostic markers for progression to chronic hepatitis or cirrhosis. Such markers ar prerequisites for therapeutic trials with potent drugs, which are only justified for patients with fulminant hepatitis and patients with progression t chronicity. If the different outcome of viral hepatitis is a result of the individual thymus-derived cell function, these two categories of patients may represent the opposite extremes in lymphocytic function. Controlled clinical trials are required to evaluate the clinical effect of immunosuppression i fulminant hepatitis and immunostimulation in chroni hepatitis.

8261 SERUM IMMUNOGLOBULIN LEVELS IN HEPATITIS-B ANTIGEN-POSITIVE AND HEPATITIS-B ANTIGE NEGATIVE ACUTE HEPATITIS. (Eng.) Bersohn, I.; Ipp T.; Macnab, G. M.; Stevenson, C. M.; Miller, G. B.; Kew, M. C. (South African Inst. Medical Res. and Univ. Witwatersrand, Johannesburg 2001, South Afric *S. Afr. J. Med. Sci.* 40(1):3-8; 1975.

Because previous reports have suggested that high immunoglobulin M (IgM) concentrations may be of dia nostic value in A and B hepatitis. IgG, IgA, and I levels were measured in the sera of 73 patients wit hepatitis B antigen (HBAg)-positive acute hepatitis and 48 patients with HBAg-negative hepatitis. Ther were no significant differences between serum IgG and IgA levels in the HBAg-positive and -negative patients. The mean serum IgM level was significantly higher in the HBAg-negative patients (231 mg/100 ml) at the time of admission than that in the HBAg-positive patients (174 mg/100 ml); these levels remained significantly higher for 2-3 weeks. However, there was considerable overlap between the IgM levels in patients with and without HBAg, so that the diagnostic value of the IgM level in individual patients was limited. The mean result of the thymol turbidity test was significantly greater in the patients with HBAg-negative hepatitis (6.66 U) than those with HBAg-positive hepatitis (4.64 U), but there was considerable overlap between the values in the two groups of patients. The bilirubin, SGOT, SGPT, alkaline phosphatase, total protein, albumin, and gamma globulin levels were not significantly different in the two groups.

8262 HEPATITIS B VIRUS ANTIGENS IN ACUTE AND CHRONIC HEPATITIS AND LIVER CIRRHOSIS. CLINICAL, MORPHOLOGIC, ENZYMATIC AND IMMUNOLOGIC ANALYSIS. (Eng.) Nazarewicz, T.; Milewski, B.; Krawczynski, K.; Nowoslawski, A. (Dept. Immunopathology, State Inst. Hygiene, Warsaw, Poland). *Mater. Med. Pol.* 7(3):191-196; 1975.

The presence of hepatitis B virus (HBV) antigens in the serum and liver was compared with morphologic and clinical parameters in 235 patients with hepatitis or liver cirrhosis. Hepatitis B surface antigen (HBsAg) and hepatitis B core antigen (HBcAg) were detected in the serum and/or liver of 127 (54%) cases. Among 25 patients with acute hepatitis, 106 patients with chronic aggressive hepatitis, 18 patients with chronic persisting hepatitis, 4 patients with subacute hepatitis, and 82 patients with postnecrotic cirrhosis, the tests for HBV antigens were positive in 60%, 63%, 28%, 25%, and 50%, resp. HBV antigens were found more frequently in the liver than in the serum; the number of positive tests in the liver, serum, and liver plus serum were 68, 19, and 40, resp. Irrespective of the type of inflammation, only one antigen was found in the majority of cases (67/108): either HBsAg in the cytoplasm (42 cases) or HBcAg in the nuclei of the hepatocytes. This is thought to be due to the periodic predominance of synthesis of one or the other of the HBV antigens. This assumption was supported by the finding of the periodic appearance of HBsAg in the sera of 60 patients who were examined several times, and both HBV antigens in the liver of several patients in whom biopsy was carried out twice. In both HBV antigen-positive and -negative patients, morphologic studies of liver tissue revealed similar intensity of degenerative and inflammatory lesions in all the various forms of hepatitis and cirrhosis. Analysis of clinical symptoms and the results of biochemical tests in both groups of patients also failed to disclose any significant differences. The presence of autoantibodies, elevation of gamma globulin, immunoglobulin G (IgG), IgA, and IgM levels, and the occurrence of systemic clinical symptoms, presumably associated with circulating immunologic complexes, were also similar in both groups. The absence of diagnostically significant differences between the two groups may be taken as evidence for a common etiopathogenic mechanism responsible for the disease

8263 HBs-Ag, HBc-Ag AND VIRUS-LIKE PARTICLES IN LIVER TISSUE. (Eng.) Furuta, S.; Nagata, A.; Kiyosawa, K.; Takahashi, T.; Akahane, Y.; Koike, Y.; Sahara, T.; Iijima, Y.; Furukawa, K.; Watanabe, T.; Hara, M.; Omori, A.; Oda, M. (Second Dept. Internal Medicine, Faculty Medicine, Shinshu Univ., 3-1-1 Asahi-cho. Matsumoto, Nagano Prefecture, 390 Japan). *Gastroenterol. Jpn.* 10(3):208-214; 1975.

Immunofluorescence was used to investigate hepatitis B surface antigen (HBsAg) and hepatitis B core antigen (HBcAg) in the hepatic tissue of three patients (2 women and 1 man, aged 37-53 yr) with various liver diseases. The tissue was obtained by needle biopsy or at autopsy. Electron microscopy demonstrated viruslike particles in the nuclei. The localization of HBsAg was restricted to the cytoplasm or the surface of hepatocytes, but HBcAg was found in the hepatocyte nuclei. Hepatocytes with nuclear HBcAg were scarce in one patient in spite of the diffuse distribution of HBsAg in the liver tissue. In the other two, many hepatocyte nuclei revealed HBcAg, although the fluorescence for HBcAg was a little less than that for HBsAg. In most of the nuclei, the HBcAg displayed a diffuse granular distribution, but in some they were loose and speckled. The size of the viruslike particles was 22-27 nm in diameter. Most of them were hollow, but some were completely electron-dense, indicating that not all of the viruslike particles contained DNA. The asymptomatic HBsAg carrier with HBcAg-positive hepatocyte nuclei despite diffuse distribution of HBsAg-positive hepatocytes suggests that the hepatitis B virus infection in the carrier state results in little virus replication in the nucleus, but abundant replication in the cytoplasm. In chronic hepatitis, however, the intranuclear viruslike particles may become dominant with a concomitant decrease of viruslike material in the hepatocyte cytoplasm.

8264 SEROTYPES OF HEPATITIS B ANTIGEN (HBsAg): THE PROBLEM OF "NEW" DETERMINANTS, AS EXEMPLIFIED BY "t." (Eng.) Le Bouvier, G.; Williams, A. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Am. J. Med. Sci.* 270(1):165-171; 1975.

Recently described antigenic determinants of hepatitis B surface antigen (HBsAg) are discussed. The principal antigenic determinants of HBsAg are specified by distinct genotypes of hepatitis B virus (HBV), and include the common antigen(s), "*a*," and two pairs of subdeterminants, *d*/*y* and *w*/*r*. The members of each pair of subdeterminants are generally mutually exclusive, resulting in four primary phenotypes of HBsAg: *adw*, *adr*, *ayw*, and *ayr*. If the newer *a*(*w*) subcategories reflect differences in viral genotype, the number of phenotypes will increase to eight. Further subdivision into independent strains of HBV may eventually become feasible, on the basis of one or more of the following new HBsAg reactivities: *g*, *n*, *q*, *x*, and *t*. The requirements for accepting new reactivities as HBV-specific, and for comparing them among themselves, are discussed, using *t* as an example. A unique feature of *t* is its variable physical behavior. In overt *t*, the antigenic sites are situated at or near the Australia antigen particle surface, where they can be easily linked by immunoglobulin G molecules of anti-*t*; in cryptic *t*, the antigenic sites are able to absorb anti-*t* antibody without particle aggregation. Overt *t* reactivity is correlated with the *adw* phenotype and cryptic *t*, with the *ayw* phenotype. However, the *adr* and *ayr* phenotypes are *t*-negative. This uneven distribution may suggest that the expression of *t* is regulated by the HBV genome.

8265 ISOENZYME SPECTRUM OF LACTATE DEHYDROGENASE IN ACUTE VIRAL LIVER NECROSIS. (Rus.) Andriutsa, K. A. (Kishinev Medical Inst., Kishenev, USSR). *Klin. Med.* 54(2):57-61; 1976.

The lactate dehydrogenase (LDH) isoenzyme spectrum was studied in the sera and livers of 30 patients (10 children, 20 adults) with acute (20 cases) and subacute (10 cases) liver necrosis due to serum hepatitis (20 cases) and infectious hepatitis (10 cases). The total LDH activity and the LDH_{50} activity were increased in all patients with acute viral hepatitis prior to liver necrosis. The liver necrosis was accompanied by a significant reduction of the total LDH and LDH_{50} activities, compared with those measured before the necrosis. Further reduction of the LDH_{50} activity was observed during coma. The changes in the isoenzyme spectrum of serum LDH, and especially the changes of LDH_{50}, were more pronounced during necrosis in patients with serum hepatitis than in patients with infectious hepatitis. Compared with control patients who died of trauma, considerable reduction of hepatic fraction of LDH_{50} was measured at autopsy in patients who died of liver necrosis.

LIVER AND BILIARY TRACT

Chronic Hepatitis

286 CLASSIFICATION OF CHRONIC HEPATITIS. (Eng.) de Groote, J. (Inwendige Geneeskunde, Akaemisch Ziekenhuis St-Raphael, Capucijnenvoer 35, 000 Leuven, Belgium). *Ann. Clin. Res.* 8(3):130-38; 1976.

he genesis of the classification of chronic hepatiis is reviewed. The classification systems depend n either morphological features (macroscopic and icroscopic) or on biological features (biochemical nd immunological). Chronic hepatitis is characterzed by an inflammatory invasion of the portal tract, ollowed by inflammation of the periportal area. hen portal inflammation remains within the limiting late and the parenchyma is well preserved, chronic ersistent hepatitis is present; when inflammatory ells penetrate the limiting plate into the parenchya, chronic aggressive hepatitis is present. It has een suggested that chronic hepatitis could be a link etween acute hepatitis and cirrhosis. It has been ecommended that chronic active hepatitis be further lassified according to the presence or absence of irrhosis. Lobular hepatitis, either acute or chronc, refers to localized spotty necrosis within the obule. Portal hepatitis describes the localization f inflammatory cells within the portal tract, which may or may not be accompanied by spotty necrosis. Classification according to biological criteria is also discussed. In one study, an increased gamma globulin concentration was observed in 50% of patients with chronic persistent hepatitis (diagnosed according to morphological features) and in 89% of those with chronic aggressive hepatitis. Other studies have shown that tissue antibody levels are much higher in patients with the more progressive form of disease. In less active cases of chronic aggressive hepatitis, the incidence of hepatitis B surface antigenemia was 51%, whereas this incidence was decreased in chronic persistent hepatitis.

8287 CLASSIFICATION AND INFECTIOSITY OF CHRONIC HEPATITIS B AS DEFINED BY DANE PARTICLES IN THE BLOOD AND BY VIRUS COMPONENTS IN THE LIVER. (Ger.) Gudat, F.; Bianchi, L.; Stalder, G. A.; Schmid, M. (Institut fur Pathologie der Universitat, Schonbeinstrasse 40, CH-4056 Basel, Switzerland). *Schweiz. Med. Wochenschr.* 106(24):812-824; 1976.

A diagnostic correlation between hepatitis B antigen (HBAg) in the liver and the occurrence of Dane particles (DP) in the blood was attempted in patients with active and nonactive chronic hepatitis B virus (HBV) infection. The test sample included 27 nonactive HBV patients (group A), 13 of whom had chronic persistent hepatitis (CPH) and 14 were carriers of HBAg; 22 cases of active hepatitis (group B), 19 of whom had chronic active forms (ACH) and 3 had lobular hepatitis; and 6 renal transplant patients (group C), 4 of whom had CPH, 1 with nonspecific reactive lesions, and 1 with ACH. In group A, no HB core antigen (HBcAg) was found by immunofluorescence in 19 of the 27 patients (13 nonspecific reactive and 6 CPH). One patient was positive by electron microscopy. With one exception, all of group A showed cytoplasmic HB surface antigen (HBsAg) synthesis in 5%-80% of the hepatocytes. In 17 of the 19 HBs-positive patients, no DP could be found and in the remaining 2 cases, only a single DP appeared after repeated incubation. Four patients in group A, all with CPH, showed HBcAg (5-50% of hepatocyte nuclei) simultaneously with HBsAg (up to 40% of all cytoplasms); DP were visible in each case. There were four cases with HBc predominance (1 nonspecific reactive and 3 CPH). In group B (destructive periportal inflammation with piecemeal necrosis and lobular hepatitis), 15 of the 22 patients exhibited HBc and HBs. The remaining seven cases were negative for one antigen (5 cases) or both (2). DP were always immediately present in peripheral blood, even in tissue-negative cases. In group C, there was a general tendency to HBc and HBs of HBc type, always with DP in peripheral blood. The single ACH patient was HBc-positive, with HBs of HBc type, and exhibited a plethora of DP in peripheral blood. The relation between inflammatory reaction, HBAg expression, and DP formation is compatible with the hypothesis that chronic hepatitis B is a chronic persistent viral infection in which the host response rather than the virus itself causes the hepatitis, and in which the virus persists only due to deficient host elimination.

8288 T-LYMPHOCYTES IN THE BLOOD AND HEPATIC TISSUE IN CHRONIC ACTIVE HEPATITIS.

(Rus.) Trayanova, T. G.; Severov, M. V.; Arustamova, R. G.; Gordovskaya, N. B.; Aprosina, Z. G.; Vinogradova, L. G.; Semendyaeva, M. E. (I. M. Sechenov First Moscow Medical Inst., Moscow, USSR). *Sov. Med.* (2):45-49; 1976.

The percentages of T lymphocytes were determined in the peripheral blood and liver tissue of 10 patients with chronic persisting hepatitis, in 10 patients with other liver diseases (chronic alcoholism, functional hyperbilirubinemia, drug-induced hepatitis, hepatoma, chronic cholangitis, residual viral hepatitis, and Sjogren's syndrome), and in 35 healthy control subjects, 2 of whom underwent liver biopsy for suspected liver disease. The percentage of T lymphocytes in the blood was 34.5% in chronic persisting hepatitis, 43.3% in other liver diseases, and 59% in the controls. The percentage of T lymphocytes in the liver tissue was 52% in the active form of chronic persisting hepatitis, 43% in the other cases of chronic persisting hepatitis, 29% in other liver diseases, and 16% in the healthy controls. The increased percentage of T lymphocytes in chronic persisting hepatitis, especially in its active forms and the simultaneous decline in the peripheral blood suggest that the "hepatotropism" of T lymphocytes is a possible proof of their involvement in the path ogenesis of chronic persisting hepatitis.

8289 THE ROLE OF IMMUNODEPRESSANTS IN THE TREATMENT OF CHRONIC ACTIVE (LUPOID) HEPATITIS.

(Rus.) Tareev, E. M.; Oprosina, Z. G.; Semendiaeva, M. E.; Traianova, T. G. (I. M. Sechenov First Moscow Medical Inst., Moscow, USSR). *Vestn. Akad. Med. Nauk SSSR* (6):64-70; 1975.

The literature on immunosuppressive therapy for chronic active hepatitis is reviewed, and results of new clinical trials with such therapy are presented. Forty-seven patients received long-term therapy with a combination of azathioprine and prednisolone. Remission was achieved in 19 patient improvement was seen in 12, there was no change in 12, and progression of the disease was observed in 4. The combination of azathioprine and prednisolone was more effective and produced fewer side-effects than did the drugs separately. Ten patient who were resistant to the combination treatment received long-term antilymphocyte globulin therapy. Clinical improvement was achieved in some of these patients. These findings and the literature indicate the possibility of achieving clinical improvement and cure, and even favorable morphological changes in the liver, by immunosuppressive therapy in patients with chronic active hepatitis. Immunosuppressive therapy is indicated during the active stage of the disease, with increased serum aspartate aminotransferase activity and gammaglobulin levels, liver cell necrosis, and lymphoplasmacytic infiltration. Advanced liver cirrhosis, pronounced hepatic insufficiency, portal hypertension, chronic alcoholism, and alcohol-induced diffuse fatty degeneration constitute contraindications to immunosuppressive therapy.

8290 THE ROLE OF IMMUNOLOGICAL MECHANISMS IN CHRONIC HEPATITIS.

(Eng.) Eddleston, A. L. W. F.; Williams, R. (King's Coll. Hosp. Medical Sch., London SE 5, England). *Ann. Clin. Res.* 8(3): 162-173; 1976.

The role of immunological mechanisms in chronic hep titis is reviewed. Humoral immune responses, cellu lar immunity, immune responses to hepatitis B surfa antigen (HBsAg), the link between virus-directed responses and autoimmunity, histocompatibility anti gen B8 as a marker for defective thymus-derived (T) cell function, occurrence of multisystem involvemen and drug-induced chronic active hepatitis are discussed. The association between chronic active hep titis, primary biliary cirrhosis, and various tissu autoantibodies is well-known. Smooth muscle antibody, when detected in high titer, is most closely associated with chronic active hepatitis, but it is now realized that low titers may occur in a variety of liver diseases. Antinuclear antibodies are distinctly unusual in acute viral hepatitis. Mitochon rial antibodies are found in 90-95% of all cases of primary biliary cirrhosis. These autoantibodies probably reflect an abnormal immune system, stimulated to autoantibody production by viral- or drug-induced hepatic damage. Early studies of lymphocyte function in chronic active hepatitis and primary biliary cirrhosis showed a depression of nonspecific T cell reactivity and a hypersensitivity to liver homogenates. A high molecular weight lipoprotein derived from the human hepatocyte plasma membrane was found to precipitate immune damage to the liver. Extensive *in vitro* studies confirmed the presence of cellular hypersensitivity to the liver-specific lipoprotein in over 90% of the patients with chronic active hepatitis. HBsAg-positive chronic liver disease is relatively uncommon; one studied showed that 18% of patients with chronic active hepatitis were HBsAg-positive by radioimmunoassay. No significant differences in clinical manifestations, immunoglobulin levels, prognosis, or cellular hypersensitivity to liver-specific lipoprotein were found between the HBsAg-positive and-negative groups. Cellular hypersensitivity to HBsAg was found in over 60% of HBsAg-negative patients; this incidence approaches that in patients recovering from acute B hepatitis and suggests a link between this illness and chronic active hepatitis, whether or not HBsAg is detectable. Evidence of disease in other organs of a type which, when present alone, is considered to be autoimmune, is also found in chronic active hepatitis and primary biliary cirrhosis; the commonest are Sjogren's syndrome and renal tubular acidosis. Although most cases of drug-induced hepatitis present as acute hepatitis, oxyphenisatin and methyldopa have been implicated in the etiology in some cases of chronic active hepatitis. It is postulated that the mechanism of drug-induced chronic hepatitis closely resembles that of chronic hepatitis of other etiologies.

8291 PHYTOHAEMAGGLUTININ-INDUCED LYMPHOCYTE TRANSFORMATION AND HISTOLOGIC FINDINGS IN PATIENTS WITH CHRONIC AGGRESSIVE HEPATITIS BEFORE AND DURING IMMUNOSUPPRESSIVE THERAPY. (Eng.) Pappas, A.; von Seebach, H. B.; Schwarze, G.; Reikowski, H.; Jost, H.; Jung, M.; Scheurlen, P. G. (Medizinische Kinik, Universitat des Saarlandes, D-665 Homburg, W. Germany). *Beitr. Pathol.* 156(3):197-207; 1975.

To determine whether chronic aggressive hepatitis is an autoimmune process and to evaluate the parameters that could be used to evaluate the effect of immunosuppressive therapy in this disease, the serum immunoglobulin concentration, serum auto-antibodies, and the *in vitro* transformation potential of phytohemagglutinin-stimulated blood lymphocytes were determined in 19 patients with chronic aggressive hepatitis. In most cases, these determinations were carried out prior to and during therapy with azathioprine (2 cases), corticosteroid (2 cases), or combined therapy (15 cases). The mean incorporation of ^{14}C-thymidine following PHA stimulation was significantly lower in 15 untreated patients (2,105 disintegrations per min) in comparison with that in 47 controls (4,649 disintegrations per min, $p<0.0005$). A mean incorporation level of 3,530 disintegrations per min occurred in 10 patients who received immunosuppressive treatment. Following the cessation of treatment in four of six patients, the incorporation had decreased again to a mean level of 2,122 disintegrations per min. Anitnuclear factors and antibodies against smooth muscle were demonstrated transiently in only two patients, prior to immunosuppressive therapy.

8292 CHANGES IN SERUM LIPIDS AND SERUM LIPOPROTEINS IN ACUTE HEPATITIS. (Ger.) Mordasini, R. C.; Berthold, S.; Schlumpf, E.; Riva, G. (Medizinische propadeutische Klinik der Universitat, Tiefenauspital, CH-3004 Bern, Switzerland). *Schweiz. Med. Wochenschr.* 106(35):1173-1182; 1976.

The degree of change in serum lipids and lipoproteins and their temporal relation to phases of acute hepatitis are compared with conventional paraclinical criteria. The test group included 50 cases of acute hepatitis that were diagnosed early; of the 50, 26 were Australia antigen (Au)-positive. Both triglycerides and total lipids increased during the initial 3 weeks of illness in the Au-positive patients and normalized in the 4th week in uncomplicated cases. Serum cholesterol remained unchanged for 4 weeks, then increased slightly, except in frank cholestasis. During the acute phase, phospholipids were also normal. In Au-negative cases, the same serum patterns occurred but were much less pronounced. In Au-positive cases, α- and preβ-lipoproteins disappeared during the initial 2 weeks of the disease, and then reappeared in the 3rd week; β-lipoproteins increased, and then decreased in the 3rd week. All were normalized by the 4th week. No preβ disappearance or β elevation occurred in Au-negative patients. In cases of cholestatic involvement, there was pronounced hypertriglyceridemia and elevated cholesterol and phospholipids, which paralleled enzyme lipoprotein X and α- and preβ extinction. There was no difference between the Au-positive and -negative cases. In 6 of the 50 patients with protracted hepatitis, the same variables increased but remained elevated longer, and the same variables decreased, but remained suppressed longer. There was unequivocal parallelism in Au-positive cases between lipid modification and transaminase activity, although SGOT and SGPT did not return to normal as rapidly as did serum lipids. However, the correlation between hypertriglyceridemia and increased bilirubin, transaminases, alkaline phosphatase, and other enzymes was statistically insignificant, since lipid changes were negligible in some severely involved acute hepatitis cases or were prominent in some relatively benign phases. Transaminase and lipid-lipoprotein patterns were especially unrelated in Au-negative patients. It is concluded that serum lipid and lipoprotein assays should not be an obligate part of liver function tests.

8293 THE DIAGNOSTIC SIGNIFICANCE OF IMMUNOGLOBULIN DETERMINATION IN CHRONIC LIVER DISEASES. II. RELATIONSHIPS BETWEEN IMMUNOGLOBULIN CHANGES AND DEGREE OF ACTIVITY. (Ger.) Ortmans, H.; Wildhirt, E.; Welcke, U.; Tucke, M. (Medizinische Klinik I, Stadt-Krankenhaus, D-3500, Kassel, W. Germany). *Munch. Med. Wochenschr.* 117(50): 1975-1978; 1975.

The relation between immunoglobulins (Ig) and gamma-glutamyl transpeptidase (GGT), alkaline phosphatase (AP), and the aminotransferases (SGOT and SGPT) in chronic liver disease was explored. The clinical sample included 715 patients divided into 13 nosological categories and 60 subjects with unaffected livers. Highly significant correlations prevailed in liver fibrosis for IgA-IgG, IgM-IgG, IgG-SGOT, and IgG-SGPT. No significant correlation was found in acute or persistent hepatitis. IgA-IgG in chronic active and necrotizing hepatitis and IgG-AP in chronic persistent hepatitis were also significantly correlated. Only IgG-SGOT were significantly correlated in hepatitic, eryptogenetic, or postnecrotic cirrhosis. Positive correlations for IgG-SGOT, IgA-AP, IgG-IgA, and IgG-SGPT existed in toxic cirrhosis, while siderocirrhosis had negative significant correlations for IgM-IgA, IgM-GGT, and IgG-SGOT, with IgA-AP positive. Primary liver cancer in cirrhosis was positive for IgG-IgA, IgG-IgM, IgA-IgM, IgA-SGPT, and IgM-AP, but negative for IgA-AP. Negative significant correlations obtained for IgM-GGT, -SGPT, and -SGOT in primary hepatobiliary disease. IgA-SGPT, IgM-SGPT, IgA-SGOT, IgM-SGOT, IgA-IgM, IgG-GPT, and IgG-SGOT were significantly correlated in cholangitis, but IgA-AP and IgG-GGT were negative. In nutritionally-induced fatty liver only IgG-AP was negative, while IgA-SGOT, IgA-GGT, IgM-SGPT, IgG-IgA, and IgG-GGT were positively correlated. All values were positively correlated in toxic fatty liver, including IgA-GGT, IgA-IgG, IgA-AP, IgA-SGOT, IgG-SGOT. IgG-SGOT, IgG-SGPT, and IgM-SGOT were significantly correlated in toxic hepatitis.

8294 VIRAL ANTIBODIES AND CHRONIC LIVER DISEASE. (Eng.) Scott, B. B.; Hambling, M. H.; Losowsky, M. S. (St. James' Hosp., Leeds LS9 7TF, England). *Biomedicine [Express]* 25(5):163-167; 1976.

Serum rubella, measles, and cytomegalovirus antibodies were determined in 69 patients with chronic liver disease and compared with those of age-matched controls. There were 33 patients with chronic active hepatitis (CAH), 16 with cryptogenic cirrhosis, and 20 with alcoholic cirrhosis. All three antibodies were significantly increased in CAH, and rubella antibodies were increased in patients with cryptogenic cirrhosis, but to a lesser extent. None of the antibodies was increased in patients with alcoholic cirrhosis. There was no correlation between increased antibody titers and the use of steroids. In CAH and alcoholic cirrhosis patients, there was no correlation between increased antibodies and the presence of portal systemic shunts (surgical or definite esophageal varices), and in the patients with cryptogenic cirrhosis, there was no correlation between antibody titer and surgical shunts, compared with normal shunts. In the patients with CAH, there were significant correlations between increased measles antibodies and positive tests for smooth muscle antibody ($p<0.01$) and antinuclear factor ($p<0.01$), but not for mitochondrial antibody. The findings suggest that the elevated titers are not the result of steroid therapy, liver damage, or of portal systemic shunting, but that they may be specifically associated with CAH.

8295 CHROMOSOMAL ABNORMALITIES IN LYMPHOCYTES FROM CHRONIC HEPATITIS PATIENTS (LONG-TERM CULTURES) [Abstract]. (Eng.) Fasce, L.; Vianello, M. G.; Tolentino, P. (Dept. Pediatrics, Univ. Genova, Genova, Italy). *Digestion* 12(4/6):303; 1975

Alcoholic Liver Disease

300 RELEVANCE OF BIOCHEMISTRY IN DIAGNOSIS AND
DEVELOPMENT OF ALCOHOLIC LIVER DISEASE.
Ger.) Ortmans, H.; Eisenberg, K. (Medizinische
linik I, Stadtkrankenhaus, Monchebergstrasse 42,
500 Kassel, W. Germany). *Med. Klin.* 71(9):380-384;
976.

he differential diagnostic value of certain biochem-
cal variables in liver disease is reexamined. The
atient population included 16 cases of fatty liver
f nutritional origin (FLN), 41 cases of fatty
iver of toxic origin (FLT), 52 with chronic alcohol
epatitis (CAH), and 96 with alcohol-induced cirrho-
is (AC). The γ-glutamyl transpeptidase (GGT) level
as normal in 63%, 5 times higher than normal in 31%,
nd 10 times higher than normal in 6% of the cases
f FLN. In FLT only 20% were normal, 49% were 5
imes higher, 17% were 10 times higher, and 14% were
ore than 10 times higher than normal. The SGOT was
ormal in 81% of FLN, with 19% showing fivefold ele-
ations. Normal SGOT occurred in 44% of FLT, with
9% 5 times higher and 7% 10 times higher than nor-
al. The SGPT was normal in 75% of FLN and elevated
ivefold above normal in 25%; 51% of FLT were normal
nd 49% were fivefold higher. Alkaline phosphatase
AP) was five times higher than normal in 6% of FLN
nd 20% of FLT. Bromthalein test (BT) values were
times higher than normal in 46% of the cases, and
ere 10 times higher in 8% of the FLN cases, while
6% of FLT were 5 times higher. Among the CAH only,
% had normal levels of GGT, with 54% 5 times, 17%
0 times, and 23% more than 10 times above normal.
GOT was increased 5-fold in 60%, 10-fold in 15%,
nd above 10-fold in 4%, while SGPT was elevated 5-
old in 48% and 10-fold in 6%. AP was normal in 60%
nd 5 times higher in 40%; BT was 5-fold and 10-fold
bove normal in 55% and 7%, resp. In AC, the GGT
alues were normal in 8%, with 50% 5 times above nor-
al, 10 times above normal in 21%, and in 21%, more
han 10 times above normal. SGOT was elevated 5
imes in 73%, 10 times in 5%, and more than 10 times
n 5%, while SGPT had risen 5-fold in 41%, 10-fold
n 2%, and above 10-fold in 2%. The highest AP va-
ues were found in AC, with 69% 5-fold higher, 29%
0-fold higher, and only 2% normal. There were no
ormal retention levels in AC, with BT 5 and 10 times
igher in 97% and 3%, resp. Application of dis-
riminant analysis found no biochemical distinction
ossible in fatty liver but a clear distinction be-
ween toxic hepatitis and cirrhosis was possible,
specially with BT. CAH and FLN or FLT were also
iscriminable, according to AP, SGOT, and SGGT,
ndependent of steatotic pathogenesis.

301 LIVER DAMAGE IN CHRONIC ALCOHOLICS WITH
AND WITHOUT DELIRIUM TREMENS. ITS INCI-
ENCE, SEVERITY AND REGRESSION. (Ger.) Bode, J.
h.; Woltge, E.; Kahm, O.; Korb, G. (Medizinische
niversitatsklinik, 3550 Marburg, Mannkopffstr. 1,
. Germany). *Dtsch. Med. Wochenschr.* 101(29):1081-
087; 1976.

he frequency and degree of liver trauma in chronic alcoholism is examined. The clinical sample consisted of 371 men, including 70 with icterus, 25 with gastric or duodenal ulcer, 26 with gastric resection, 7 with cholecystitis, 7 with pancreatitis, and 12 with manifest or latent diabetes. No correlation was found between the extent or type of liver damage and the rate or duration of alcohol consumption; although 85% of the sample had some degree of liver involvement. Within 1.5-4 weeks of abstinence, the most acutely affected livers began to normalize. Among the 10-yr drinkers, the patient population eventually fell from 15% to 5%; among the 10-20-yr drinkers, the population fell from 16% to 11%; and among the more-than-20-yr drinkers, it fell from 19% to 16%. Normalization of the delirium tremens group, which had the most severe liver injury, involved fewer patients. Liver biopsy in 85 cases found 51% with fatty liver, 43% with fibrosis, 21% with hepatitis, 20% with cirrhosis, 15% with cholestasis, and 10% with "hepatopathy" in the group with 15 or more years of abuse. The group with less than 15 yr of abuse induced 58% with fatty liver, 18% with fibrosis, 11% with hepatitis, 9% with cirrhosis, 11% with cholestasis, and 19% with "hepatopathy."

8302 LIVER BIOPSY AND LIVER FUNCTION TESTS IN 28 CONSECUTIVE LONG-TERM ALCOHOLICS. (Eng.) Kyosola, K.; Salorinne, Y. (Maria Hosp., Helsinki, Finland). *Ann. Clin. Res.* 7(2):80-84; 1975.

8303 INCORPORATION OF ETHANOL IN A TOTALLY LIQUID DIET: A NEW EXPERIMENTAL MODEL OF ALCOHOLIC LIVER INJURY IN THE BABOON [Abstract]. (Eng.) Lieber, C. S.; DeCarli, L. M.; Rubin, E. (Bronx Veterans Admin. Hosp., New York, NY). *J. Med. Primatol.* 4(6):334-335; 1975.

8304 EVOLUTION AND NATURE OF MALLORY'S ALCOHOLIC HYALINE BODY [Abstract]. (Eng.) Yalcin, S.; Schaffner, F. (Medical Clinic, First Medical Faculty, Istanbul, Turkey). *Digestion* 12(4/6): 363; 1975.

8305 THE PATHOGENESIS OF ALCOHOLIC HEPATITIS AND CIRRHOSIS. Strickland, R. G.; Miller, J. V. (Univ. New Mexico, Sch. Medicine, Albuquerque, NM). *Aust. N.Z. J. Med.* 6(1):78-81; 1976.

8306 CHOLESTATIC LESIONS OF THE LIVER OF ALCOHOLIC ETIOLOGY (MORPHOLOGICAL STUDY). (Rus.) Bliuger, A. F.; Kartashova, O. I.; Maksimova, L. A.; Zaltsmane, V. K.; Saldava, L. A.; Golubov, I. S. (Riga Medical Inst., Riga, USSR). *Arkh. Patol.* 38(2):72-77; 1976.

Cirrhosis

8307 LATE RESULTS AFTER SO-CALLED PRESSURE-ADAPTED HEPATIC ARTERIALIZATION AND PORTACAVAL SHUNT. (Ger.) Zimmermann, H.-B.; Burger, K.; Wagner, K.; Schneider, G.; Schimmelpfennig, W.; Schmidt, P. K. H. (II. Medizinische Klinik des Bereiches Medizin (Charite), Humboldt-Universitat, DDR-104 Berlin, Schumannstr. 20/21, E. Germany). *Zentralbl. Chir.* 100(1):40-46; 1975.

The postoperative onset of an acute portacaval encephalopathy in one patient and icterus in two other patients following portal vein arterialization via iliac-portal saphenous bypass prompted reconsideration of the operation. Four cirrhotic patients had received the operation. All patients were improving postoperatively until one 47-yr-old woman succumbed 6 weeks later from liver failure and intractable hydrops universalis; two other cases developed hemolytic icterus. All had slightly elevated alkaline phosphatase levels. The elevated pressure in the arterialized portal vein stump was 60-100 mm Hg 12 months postoperatively, compared to 23-32 mm Hg before the shunt and 20-30 mm Hg immediately after arterialization. Saphenous bypass angiography showed typical dilation of the portal stump and portal vein branches bilaterally, with the peripheral portal branches constricted. Small portal vessels were no longer demonstrable, confirming reduced vascularization of certain parenchymal areas. The liver was reduced in size, and heavy stromal increases were found histologically. The maintenance of pressure adaptation in the intrahepatic portal vein, remains unsolved.

8308 EFFECT OF LIGATION OF THE SPLENIC ARTERY ON PORTOHEPATIC CIRCULATION. (Rus.) Patsiora, M. D.; Ershov, Yu. A.; Kharazov, F. V.; Danilyanz, E. V. (All-Union Scientific Res. Inst. of Clinical and Experimental Surgery, Moscow, USSR). *Khirurgiia (Mosk.)* (11):82-85; 1975.

The therapeutic effect of splenic artery ligation in 28 patients with extrahepatic portal hypertension and 52 patients with intrahepatic portal hypertension is described. Additional surgical interventions included splenorenal anastomosis in 16 cases, gastrotomy in 17, omentohepatodiaphragmopexy in 12, displacement of the spleen into the retroperitoneal cavity in 29, and denervation of the hepatic artery in 6. Blood flow and blood chemical examinations revealed splenic artery ligation to be effective as an auxillary means of hepatic arterialization in patients with initial liver cirrhosis, but not in patients with extrahepatic portal hypertension or at advanced stages of liver cirrhosis. Ligation of the splenic artery is not recommended in cases of negative and aminophylline tests. Ligation of the splenic artery may be justified in patients with extrahepatic portal hypertension in case of hemorrhage from the esophageal veins.

8309 MORPHOLOGICAL FEATURES: THEIR USEFULNESS IN THE DIAGNOSIS, PROGNOSIS, AND MANAGEMENT OF CIRRHOSIS. (Eng.) Baggenstoss, A. H. (No affiliation given). *Clin. Gastroenterol.* 4(2):227-246; 1975.

The contribution of pathologic morphology to the diagnosis, prognosis, and management of cirrhosis is reviewed. The reliability of a histological diagnosis depends on the nature of the studies, the size of the biopsy and the manner in which it is taken, and on the type of cirrhosis. A correct classification can be achieved to a variable extent on the basis of morphological pattern, degree of development, activity of the inflammatory process, and, most importantly, etiological factors. Four morphological patterns have been identified: micronodular, macronodular, mixed micro- and macronodular, and incomplete septal (multilobular). Etiological factors provide the most useful classification, and a summary is given of typical morphological changes associated with distinct etiological types: alcoholic cirrhosis, posthepatitic cirrhosis, secondary (obstructive) biliary cirrhosis, primary biliary cirrhosis, Wilson's disease, and cirrhosis associated with α_1-antitrypsin deficiency. Once cirrhosis has developed, the difficulty of ascertaining the etiology is compounded by the gradual disappearance of the various cytological and histological alterations characteristic of the original injury. The importance of the pathological impression of etiology to clinical management is emphasized.

8310 EXTRAHEPATIC MANIFESTATIONS OF CIRRHOSIS. (Eng.) Martini, G. A. (No affiliation given). *Clin. Gastroenterol.* 4(2):439-460; 1975.

Manifestations of cirrhosis in organs and tissues other than the liver are reviewed. A variety of skin changes may occur, and vascular changes include telangiectasias, the arterial spider, white spots, altered reaction to UV light, palmar erythema, Dupuytren's contracture, and clubbing. Widespread alterations in the circulatory system include changes in the hepatic and splanchnic vasculature, the systemic and pulmonary vasculature, and the heart. Functional renal failure is a frequent terminal event in chronic liver decompensation. It may occur abruptly or gradually, over weeks and months, and is characterized by ascites, edema, and signs of dehydration. Among the digestive organs, the parotid gland may be enlarged, accompanied by hypersecretion and a high rate of amylase production. The pancreas may have a high secretory volume, and maldigestion and malabsorption are not uncommon. Deficient absorption of lipid-soluble vitamins and of calcium occurs, and reduced basal gastric secretion has been observed. Peptic ulcer incidence is increased, and cholelithiasis is more common than in matched noncirrhotic patients. Abdominal hernia often precedes ascites. The most prominent alteration in bone is osteoporosis. Many endocrine disturbances are related to altered catabolism or inactivation of hormones. Gynecomastia, alteration of secondary hair distribution, loss of libido, impotence, and testicular atrophy are frequently encountered in men, and women frequently experience amenorrhea or dysmenorrhea, cystic mastitis, or acne. Sterility is almost universal. Adrenal dysfunction is suggested clinically, but the exact nature of this abnormality is not understood. Anemia, leukopenia, and thrombocytopenia are common. Hemorrhagic disorders occur in about 5%, and clotting factor deficiency is common. Cirrhotic patients are more susceptible to infection, particularly with gram-negative bacteria. Several types of neuropsychiatric syndromes, or portosystemic encephalopathy, have been described in association with the disease. Acute encephalopathy is reversible, but the chronic form is irreversible.

8311 PRIMARY BILIARY CIRRHOSIS. (Eng.) Schaffner, F. (No affiliation given). *Clin. Gastroenterol.* 4(2):351-366; 1975.

The etiology, pathology, clinical picture, diagnosis, immunological aspects, and treatment of primary biliary cirrhosis are reviewed. The disease most frequently affects middle-aged women and is associated with severe pruritis. Radiographically or upon direct cholangiography, the smaller intrahepatic ducts are diffusely or focally narrowed or shortened and show diminished branching. Serum alkaline phosphatase is consistently elevated, to as high as 25 times normal. Serum bile acids are also elevated, and they appear to be related to the pruritis. Serum proteins are frequently lower than normal, as is prealbumin and hemopexin. Complement-fixing circulating antibodies directed against ductal cell cytoplasm and antinuclear antibodies have been demonstrated, as well as antibodies directed against mitochondria. The latter are the basis of a diagnostic test for this disease. Considerable evidence has linked primary biliary cirrhosis to an altered cell-mediated immune response. This disease may also be associated with other diseases of altered immune responsiveness, e.g., scleroderma and Sjogren's syndrome, and, to a lesser extent, rheumatoid arthritis and lupus erythematosis. Intensive studies of the relation between primary biliary cirrhosis and hepatitis B have shown that hepatitis B plays no role in its etiology. The initial injury is to the small interlobular or septal bile ducts. As these are destroyed, bile ductules proliferate, only to be eventually destroyed too, with the production of scar tissue. This is followed by true cirrhosis. Bile duct destruction in the absence of advanced cirrhosis or chronic aggressive or even acute viral hepatitis is considered pathognomonic of primary biliary cirrhosis. Since the underlying etiologic agent is unknown, therapy has been empirical. Diet therapy for hypercholesterolemia has not been helpful, but a low cholesterol intake and the use of polyunsaturated fats are suggested. Cholestyramine, a bile acid-sequestering resin, and anabolic steroids have been useful in controlling pruritis. Bone problems can be minimized by parenteral vitamin D supplements. Corticoids and immunosuppressive therapy have not been helpful in controlling the underlying disease process.

8312 A STUDY OF THE ENDOCRINE MANIFESTATIONS OF HEPATIC CIRRHOSIS. (Eng.) Baker, H. W. G.; Burger, H. G.; de Kretser, D. M.; Dulmanis, A.; Hudson, B.; O'Connor, S.; Paulsen, C. A.; Purcell, N.; Rennie, G. C.; Seah, C. S.; Taft, H. P.; Wang, C. (Medical Res. Center, Prince Henry's Hosp., Melbourne, Australia). *Q. J. Med.* 45(177):145-178; 1976.

To test the hypothesis that the primary abnormality in cirrhosis is a reduction in the capacity of the liver to degrade estrogens, the clinical features and hormonal abnormalities of 117 cases of liver cirrhosis were surveyed. Compared with healthy men of similar ages, the patients had significantly lower mean metabolic clearance rates of testosterone (621 l/day versus 1,043 l/day, $p<0.001$), lower plasma production rates of testosterone (3.18 mg/day vs. 6.74 mg/day, $p<0.001$), lower total plasma testosterone levels (range=1.71-8.05 ng/ml versus 3.34-10.75, $p<0.001$), and lower mean free testosterone levels (31.0 pg/ml versus 98.4 pg/ml, $p<0.001$). In addition, the mean testosterone level rose only 40% in the cirrhotic patients after they received 1,500 U of human chorionic gonadotrophin twice daily for 4 days, whereas it rose 149% in the normal men ($p<0.001$). In comparison with the controls, the patients had higher estradiol levels (up to 103 pg/ml versus a maximum of 39 pg/ml, $p<0.001$), higher luteinizing hormone levels (0.5-14.3 mIU/ml versus 0.6-3.3 mIU/ml, $p<0.001$), higher follicle stimulating hormone levels (0.2-37.7 mIU/ml versus 0.5-8.0 mIU/ml, $p<0.01$), and higher binding capacities of sex steroid binding globulin (10.4×10^{-8} M versus 5.1×10^{-8} M). The peripheral conversion of testosterone to estradiol was also significantly increased in the cirrhotic patients. However, the metabolic clearance and plasma production rates of estradiol were not significantly different from those of healthy controls. Patients who were severely ill with liver failure and one patient with hemochromatosis had low levels of luteinizing hormone and follicle stimulating hormone and subnormal responses to clomiphene and luteinizing hormone-releasing hormone. Higher plasma estradiol levels were found in patients with gynecomastia and spider nevi than in those without these signs. The clinical features of androgen deficiency were only poorly related to the low testosterone levels, and production rates and longitudinal studies indicated that the hormonal levels, endocrine features, and severity of the liver disease could change independently. It is concluded that the clearance of estradiol from plasma is not limited by liver disease in all patients and that reduced degradation of estrogens is not the initial event in the sequence leading to the hormonal abnormalities of cirrhosis.

8313 HUMORAL IMMUNITY AND CELLULAR HYPERSENSITIVITY IN LIVER CIRRHOSIS. (Rus.) Makarevich, Ya. A.; Zaklyakova, L. V.; Afanasiev, S. S.; Zhabotinskaya, T. M. (Astrakhan Medical Inst., Astrakhan, USSR). *Sov. Med.* (5):99-103; 1975.

Humoral immunity and cellular hypersensitivity were studied in 30 patients with liver cirrhosis (21 cases of portal cirrhosis, 8 cases of postnecrotic cirrhosis, and 1 case of biliary cirrhosis). Patients with other diseases and healthy subjects served as controls. The lymphocyte blast transformation test revealed transformation of 50.7% of the lymphocytes sensitized to hepatic antigen; there was a spontaneous transformation rate of 19.6%, as opposed to less than 1% in the control. Rebuck's dermographic test revealed a highly significant increase in the percentage of cells of the reticulohistiocytic system. The leukocytolysis stimulation reaction was positive in moderately active cirrhosis and weakly positive in less active forms of the disease. Fleck's leukocyte agglomeration test was positive in moderately active forms of cirrhosis. The local hemolysis test was highly positive in cirrhosis of low activity. Humoral autoantibodies to hepatic antigen were found in 71.4% of the patients. There was no correlation between the incidence of titer of antibodies and the degree of the allergic cellular reactions. The results suggest that autoallergy in liver cirrhosis is of a mixed cellular-humoral nature, which is confirmed by experimental findings, including the transfer of allergy through the agency of blood cells and sera.

8314 RELATION OF STEATOSIS TO CIRRHOSIS. (Eng.) Thaler, H. (No affiliation given). *Clin. Gastroenterol.* 4(2):273-280; 1975.

The causes of steatosis of the liver, or fatty liver, and its possible relation to hepatic cirrhosis are discussed. In one series of 10,970 liver biopsies, the incidence of steatosis was 26.5%. In the overpopulated and underdeveloped countries of the tropics, steatosis of the liver from protein deficiency (kwashiorkor) is probably the most frequent type, but in North America and Europe, steatosis results most often from overnutrition. In biopsy material, alcoholism is the most frequent cause because biopsy is the only reliable method of ascertaining the degree of hepatic damage in this condition. Less frequent causes are hyperlipoproteinemia and drugs (e.g., tetracycline and corticoids). In 2%-3%, the cause is unknown. Hepatic steatosis disappears quickly and completely once the cause is removed. This is true in kwashiorkor as well as in alcoholism. Cirrhosis results from the cause of the steatosis, and not from the fat accumulation itself. There is no evidence in man that cirrhosis results from nutritional deficiencies alone. Even the cirrhosis that occurs after small bowel bypass operations appears to be the result of metabolic rather than nutritional disturbances.

8315 STUDIES ON LIVER CIRRHOSIS IN AOMORI PREFECTURE WITH SPECIAL REFERENCE TO EPIDEMIOLOGY. (Jpn.) Nara, H. (Hirosaki Univ. Sch. Medicine, Hirosaki, Japan). *Hirosaki Med. J.* 26(3/4): 417-426; 1974.

8316 SPONTANEOUS REVERSAL OF PORTAL FLOW IN CIRRHOSIS. ANGIOGRAPHIC STUDY OF 15 CASES. (Fre.) L'Hermine, C.; Paris, J. C.; Villoutreix, H.; Dehaene, J. L.; Lemaitre, G. (C.H.U., F 59000 Lille, France). *Radiol. Electrol.* 56(6/7):491-503; 1975.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

8325 BILIARY LITHOGENESIS AND BILE ACID METABOLISM UNDER THE INFLUENCE OF β-SITOSTEROL. (Ger.) Begemann, F.; Bandomer, G.; Herget, H. J. (No affiliation given). *Z. Gastroenterol.* 14(Suppl.): 240; 1976.

The lithogenic effect of β-sitosterol, a phytosterol that inhibits intestinal cholesterol resorption without self-resorption, is explored. Administration of 12 g/day of β-sitosterol (SS) induced a 10-15% decrease in lithogenesis inside of 6 weeks in six of seven subjects. The average depression was 10% ($p<0.05$). The rate of primary bile acid synthesis, total enterohepatic bile acid pool, and its components (cholic, chenodeoxy, and deoxycholic acids) varied and could not be correlated with the diminished lithogenesis. The results demonstrate the importance of SS in dissolving cholesterol stones; however, the elevated cholesterol solubility of bile under SS cannot be explained by increased bile acid formation alone.

8326 PRIMARY SCLEROSING CHOLANGITIS. (Rus.) Potashov, L. V.; Krasnov, E. I. (I. P. Pavlov First Leningrad Medical Inst., Leningrad, USSR). *Klin. Med.* 54(2):139-141; 1976.

The clinical features and treatment of primary sclerosing cholangitis in a 36-yr-old woman are described. The patient presented with subicteric sclera, slight pain in the right hypochondrium and in the epigastric region, a high urinary bile pigment level, and bilirubinemia. Surgery, performed for suspected mechanical obstruction of the bile ducts, revealed sclerosis and occlusion of the common hepatic duct. Recanalization, drainage, cholecystostomy, and choledochostomy were performed. Adjuvant desensitizing and antiinflammatory therapy was also given. Practically complete recovery and reduction of bilirubinemia were achieved after protracted hepatobiliary insufficiency. The patient is in satisfactory condition 14 months after surgery.

8327 CAUSE OF DEATH OF PATIENTS WITH CHOLELITHIASIS NOT SUBJECTED TO SURGERY. (Rus.) Dmitriev, A. E.; Tatevosian, A. S.; Mezhenkov, E. P. (I. M. Sechenov First Moscow Medical Inst., Moscow, USSR). *Klin. Med. (Mosk.)* 53(11):69-73; 1975.

The causes of death for 65 patients with cholelithiasis who refused to undergo surgery or were not operated because of highly impaired health status or erroneous diagnosis were analyzed. There were 14 patients under 60 yr of age and 51 over 60. The causes of death were necrosis of the pancreas in 15 cases (1 patient under 60, 14 over 60), peritonitis in 13 (2 and 11, resp.); hepatorenal insufficiency in 12 (8 and 4, resp.); cholangitis in 8 (1 and 7, resp.); sepsis in 7 (2 and 5, resp.); and poisoning, pneumonia, thromboembolism of the pulmonary artery, and hemorrhagic infarction of the lung in 3, 4, 2, and 1 patient, resp., over 60 yr of age. The findings indicate that the necessity of early operation after the first attack of acute calculous cholecystitis and of emergency surgery for pyonecrotic processes in the gallbladder. Surgery is especially recommended for elderly and senile patients in whom destructive cholecystitis can bring about various types of pyoseptic complications in the biliary tract and cardiopulmonary tissue.

8328 SELECTION OF GALLSTONE PATIENTS FOR LITHOLYSIS. (Ger.) Wolpers, C. (Lubeck, W. Germany). *Leber Magen Darm* 6(1):43-46; 1976.

Factors in selecting gallstone patients for litholysis are reviewed and discussed. A retrospective survey of 825 cholecystectomized patients with stones illustrates the types of selection criteria for potential candidates. Contraindications, occurring in 628 patients, included cystic duct occlusion (198 cases), too large of a stone volume (151), single stones with diameters exceeding 20 mm (86), heavy calcium content (77), pigment stones (63), choledocholithiasis (37), partially cirrhotic bladder (10), and adenomyomatosis or polyps with stones (6). Indications, occurring in 197 patients, included single cholesterol stones with diameters 20 mm or less (50 patients) and multiple cholesterol stones of equal (99) or unequal (48) size. About 94% of human stones have predominantly cholesterol compositions; 6% are pigmented, two-thirds of which have elevated calcium carbonate deposition. If stone dimensions are below 15 mm, radiological differentiation of about 2% of the calcium-deficient pigment stones from about 70% of the multiple cholesterol stones is impossible. The suspension properties of stones in the contrast medium is often more decisive than size, shape, contour, specific weight, or radiolucency; fresh stones are suspended and pigment or old cholesterol stones are sedimented. Cholesterol stones also grow five times more rapidly than pigment stones. The age of a stone is roughly equivalent to its diameter. Both a patent cystic duct and adequate reaction space in the gallbladder are required for successful litholysis. Chenodeoxycholic acid is mentioned as the litholytic agent of choice.

8329 EARLY DIFFERENTIAL DIAGNOSIS OF JAUNDICE WITH THE AID OF RETROGRADE CHOLANGIOPANCREATOGRAPHY THROUGH A FIBERDUODENOSCOPE. (Rus.)

Panchenkov, R. T.; Semenov, V. V.; Stanulis, A. I.; Vasilyev, Yu. D. (N. A. Semashko Moscow Medical Inst. Stomatology, Moscow, USSR). *Klin. Med.* 54(2): 75-79; 1976.

The differential diagnosis of obstructive jaundice by retrograde cholangiopancreatography through a fiberduodenoscope was performed in 55 adults with various diseases of the liver, bile ducts, and pancreas, complicated by obstructive jaundice. The cholangiopancreatographic differential diagnosis of obstructive jaundice was successful in 41 cases. Diagnosis was possible by duodenoscopy and spot biopsy from the region of the ampulla of Vater in 12 cases of inflammation of the ampulla of Vater. The examination failed in two cases. Chronic calculous cholecystitis with choledocholithiasis was diagnosed by retrograde cholangiopancreatography in 11 cases, choledocholithiasis in 17, stenosis of the choledochoduodenal anastomosis in 1, chronic recurrent pancreatitis in 5, and cicatricial stricture of the common bile duct in 7. Forty-four patients underwent surgery and three, laparoscopy. Intraoperative cholangiography, choledochoscopy, laparotomy, and autopsy fully confirmed the retrograde cholangiopancreatographic diagnosis of obstructive jaundice. No complications were observed during or after the procedure.

8330 SURGICAL MANAGEMENT OF HIGH OBSTRUCTION OF THE BILIARY TRACT. (Rus.)

Artem'eva, N. N. (Leningrad Inst. Hygiene and Medicine, Leningrad, USSR). *Khirurgiia (Mosk.)* (11):98-103; 1975.

One hundred twenty-eight operations were performed in 114 patients for high obstruction of the biliary tract. The obstruction was due to cicatricial stricture of the hepatic bile duct in 32 cases, to cancer of the gallbladder in 44, to cancer of the hepatic bile duct in 28, to cancer metastasis to the lymph nodes of the hepatoduodenal ligament in 8, and to benign tumors of the hepatic bile duct in 2. The surgical method was selected as a function of cholangiographic findings and the stage of jaundice. The stump of the hepatic duct was anastomosed with the duodenum in a Y-shaped drainage (8 operations), or with a Y-shaped excluded jejunal loop (16 operations) in some of the patients with cicatricial stricture. The lobular ducts were anastomosed with the jejunum on a Y-shaped drainage in five cases, cholangiohepatogastrostomy was performed in three cases, and subcutaneous fistuloenterostomy with a Y-shaped excluded intestinal loop was performed in six. Six patients died following surgery. Among the 82 tumor patients, radical surgery (resection of the hepatic duct or cholecystectomy with resection of the bile duct or of the liver and bile duct) was performed in four cases, while the surgery on the hepatic and extrahepatic bile ducts was palliative in all other cases. The postoperative mortality was 22 patients, the average survival was 8 months. In patients with cicatricial stricture, the best results were obtained with anastomosis between the extrahepatic bile ducts and a Y-shaped excluded intestinal loop. If the ducts of the right and left hepatic lobes were communicating, there was sufficient drainage of the ducts of one lobe only. Otherwise, both lobes had to be drained.

8331 METHOD AND DIAGNOSTIC POTENTIAL OF PERITONEOSCOPIC GALLBLADDER PUNCTURE. (Ger.)

Ropertz, S.; Wagner, K. (Krankenhaus St. Rochusstift, Bad Mergnetheim, W. Germany). *Leber Magen Darm* 6(1):19-24; 1976.

Experiences with diagnostic peritoneoscopic gallbladder puncture are described. Only one complication, a local peritonitis, occurred among 110 puncture procedures. The site of choice for puncture is either the medial part of the middle of the gallbladder or the cranial half of the body. The flexible needle, 15 cm in length with an external diameter of 0.8 mm and internal diameter of 0.5 mm, can be use for bile aspiration or transvesicular cholecystocholangiography. The majority of positive transvesicular visualization of stones was negative in conventional radiology; one radiological picture was too equivocal for interpretation, and cholecystolithiasis had already been diagnosed in two others. In the punctur sample, conventional radiology was positive in 14 cases of gallstones: 3 with ductal stones, 7 with combined bladder-duct lithiasis, 4 each with various bladder and ductal modifications, and cases of biliar infections, with or without lithiasis. Indications for peritoneoscopic puncture with cholecystocholangiography include iterus of nuclear origin, negative cholecystograms, dyskinetic bladder, occult pain without radiological correlation, and recent inflammation or serous changes.

GENERAL

8357 LONG-TERM OBSERVATIONS IN ENDOSCOPIC LASER COAGULATIONS IN THE GASTROINTESTINAL TRACT. (Eng.) Fruhmorgen, P.; Kaduk, B.; Reidenbach, H.-D.; Bodem, F.; Demling, L.; Brand, H. (Med. Univ.-Klinik, D-852 Erlangen, Krankenhausstr. 12, W. Germany). *Endoscopy* 7(4):189-196; 1975.

Long-term studies were carried out in dogs to determine whether late morphological changes follow light coagulations with the argon laser in the gastrointestinal tract. One hundred sixteen lesions were created in the esophagus, stomach, and small and large intestine. The coagulations were performed through a fiberendoscope, and a flexible plastic light guide was used. Neither peritonitis nor death due to perforation occurred in any of the animals. Nineteen lesions were examined endoscopically at 6, 12, 18, 24, 35, and 41 days after coagulation; all but a single lesion had healed by the 12th day. The remaining 45 lesions were examined histologically after 24 hr, 14 days, and 21 days. At 24 hr, the epithelium of the lesions in all areas of the gastrointestinal tract was eroded and ulcerated. In the margins of necrotic areas, there was WBC infiltration. The lumen of the submucosal vessels was thrombotic. After 14 days, scarring with incipient epithelialization and the formation of capillaries in granulation tissue was seen. After 21 days, re-epithelialization was well advanced or complete in all lesions. Light coagulation has the following advantages over electrocoagulation in the treatment of patients: no direct contact with the tissue, and thus no sticking of the probe tip to the coagulated tissue, the ability to control the procedure visually, no flow of current through the body tissues, greater therapeutic range, selective absorption, autoregulation of the depth of penetration, rapid and effective coagulation, and less blood loss.

8358 INVOLVEMENT OF THE SMALL INTESTINE IN SYSTEMIC MAST CELL DISEASE. (Eng.) Scott, B. B.; Hardy, G. J.; Losowsky, M. S. (St. James's Hosp., Leeds, England). *Gut* 16(11):918-924; 1975.

The case of a patient with mast cell infiltration of the small intestine in the absence of the skin involvement characteristic of mast cell disease is presented. The results of quantitative studies of the mast cells in the small bowel mucosa of 11 patients with untreated celiac disease and 10 controls are also reported. The patient, a 47-yr-old woman, had a 10-yr history of intermittent abdominal pain and diarrhea. Other clinical features that supported the diagnosis of mast cell disease were: histaminuria; increased urinary heparinoids; episodes of facial flushing; increased numbers of mast cells in the small bowel mucosa; and subtotal villous atrophy, responsive to a gluten-free diet. She had persistent malabsorption, the fecal fat levels ranging between 42 and 53 mmol/24 hr. Other features of celiac disease were raised levels of gluten antibodies and the presence of histocompatibility antigen HL-A8. There was no skin involvement, and a skin biopsy showed no excess of mast cells. The patient responded to treatment with propantheline, antihistamines, analgesics, and hyoscine. Jejunal biopsies from the patients with untreated celiac disease and from the controls revealed that the average number of mast cells in the lamina propria of both groups was two per high-power field (HPF). Because previous studies have shown that the finding of a level of more than six mast cells per HPF in the skin is suggestive of mast cell disease, the authors propose that the presence of more than this number of mast cells in the lamina propria is suggestive of mast cell disease.

8359 LOPERAMIDE IN CHRONIC DIARRHEA AND AFTER ILEOSTOMY: A PLACEBO-CONTROLLED DOUBLE-BLIND CROSS-OVER STUDY. (Eng.) Tytgat, G. N.; Huibregtse, K.; Meuwissen, S. G. M. (Div. Gastroenterology, Univ. Amsterdam, Amsterdam, Netherlands). *Arch. Chir. Neerl.* 28(1):13-20; 1976.

The effectiveness of loperamide in the treatment of diarrhea of various etiologies was tested in a double-blind study of 15 patients with diarrhea and 20 patients with well-established ileostomies. Loperamide, at a median dose of six (range 2-7) 2-mg capsules per day, was successful in controlling diarrhea in 11 of the 15 patients with chronic diarrhea; the 11 patients included 2 patients with ulcerative colitis, 1 patient with Crohn's disease of the colon, 5 patients with irritable colon, 1 patient with postvagotomy diarrhea, 1 patient who had undergone proctocolectomy, and 1 patient who had undergone colectomy and had proctitis. This treatment failed in one patient who had taken large amounts of laxatives, in two patients with severe cholerrheic diarrhea due to ileotransversostomy with bypass of the terminal ileum and right colon, and in one patient with diarrhea of unknown etiology. In the successfully treated patients, a statistically significant amelioration of stool consistency ($p<0.05$) and stool frequency ($p<0.01$) and a trend towards a lessening of abdominal cramps ($p<0.10$) was found. In the ileostomy patients, the median (and range) of daily fecal weight were 645 (100-2,620), 500 (80-2,010), and 660 (180-2,020) g, during the drug-free, loperamide, and placebo periods, resp., of the study. Daily fecal outputs were significantly lower during treatment with loperamide than during either the drug-free or placebo treatment ($p<0.001$). The median daily ileostomy output decreased by 22% during treatment with loperamide. Many ileostomy patients noticed an increased urinary production and experienced an improvement in ileostomy care during loperamide treatment. The results suggest that loperamide is useful and safe for the treatment of chronic diarrhea and in the treatment of ileostomy patients.

8360 ROLE OF PLASMA FILTRATION IN THE INTESTINAL FLUID SECRETION MEDIATED BY INFECTION WITH Salmonella typhimurium. (Eng.) Giannella, R. A.; Rout, W. R.; Formal, S. B.; Collins, H. (Dept. Gastroenterology, Veterans Admin. Hosp., Lexington, KY 40506). *Infect. Immun.* 13(2):470-474; 1976.

To study the mechanism of intestinal fluid secretion elicited by invasive bacteria, the plasma-to-lumen clearance of two different-sized molecules, ^{54}Cr-albumin and ^{14}C-mannitol, was measured in the *in vivo* rabbit ileal loop and *in vivo* rhesus monkey models of salmonellosis. The electrolyte and protein concentration of rabbit ileal fluid evoked by *Salmonella typhimurium* was measured and compared to cholera toxin- and cholera toxin-EDTA-mediated ileal fluids. In the rabbit ileal loop model, the clearance of neither molecule was increased when compared to cholera toxin-exposed loops. In the monkey, clearance of ^{14}C-mannitol into the jejunum, ileum, and colon did not differ from that observed in control animals. These data indicate that *S. typhimurium* did not alter the permeability characteristics of the intestinal mucosa substantially and that plasma filtration through a damaged, more-permeable mucosa does not contribute to the *Salmonella*-induced intestinal secretory process.

GENERAL

Parasitology

8401 TREATMENT OF AMOEBIC RECTOCOLITIS: COMPARISON OF THE EFFICACY OF TINIDAZOLE AND METRONIDAZOLE WITH HIGH DOSAGE OVER A SHORT TERM. (Eng.) Manrique, E. C.; Gallegos, G. L.; Verdin, F.; Montero, S. (Hosp. General del Centro Medico Nacional IMSS, Mexico City, Mexico). *J. Int. Med. Res.* 3(5):314-318; 1975.

The therapeutic value of tinidazole was compared with that of metronidazole (both at 2.4 g/day, p.o., 2 days) in 20 patients with amebic rectocolitis. In the 10 patients treated with tinidazole, the symptoms of dysentery disappeared after 4 days. Side-effects (headache and tympanites) occurred in two patients treated with tinidazole. After 6 days, rectoscopy showed superficial lesions in two patients, and one of these patients also had ulcers. The rectal mucosa was normal in all 10 patients treated with tinidazole after 11 days. Colonoscopy on the third day revealed nonulcerated superficial lesions in one of three patients; colonoscopy on the 10th day showed no lesions in three patients, and colonoscopy on the 21st day showed a normal mucosa in all of four patients. Of the 10 patients treated with metronidazole, one patient had persistent dysentery. Two patients experienced dizziness and headache. Six days following the initial treatment, rectoscopy showed a normal mucosa in four patients, nonulcerated superficial lesions in one, and ulceration in five. After 11 days, only one patient still had mucosal lesions. This patient died due to the severity of the amebic disease, anemia, diabetes, cerebral vascular accident, and disseminated intravascular coagulation. Colonoscopy on the 10th day showed an abnormal mucosa in two of three patients. After 3 weeks, only one of four patients had an abnormal colonic mucosa. Laboratory tests were performed in 19 patients. All had normal liver function. Of the seven patients who had an abnormal blood count before treatment, the blood count returned to normal after treatment in five. On the 51st day after treatment, three papients who had received metronidazole and two patients who had received tinidazole continued to emit *Entamoeba histolytica* cysts. The results demonstrate that the therapeutic efficacy of both drugs was similar at equal doses, but tinidazole caused a more rapid healing of colonic lesions caused by the vegetative forms of the parasite.

8402 COMPARATIVE SENSITIVITY AND SPECIFICITY OF THE CASONI INTRADERMAL AND THE IMMUNOELECTROPHORESIS TESTS FOR THE DIAGNOSIS OF HYDATID DISEASE. (Eng.) Yarzabal, L. A.; Schantz, P. M.; Lopez-Lemes, M. H. (Service d'Immunologie et de Biologie Parasitaire, Place de Yerdun, 5900-Lille, France). *Am. J. Trop. Med. Hyg.* 24(5):843-848; 1975.

The sensitivity of the immunoelectrophoresis (IEP) test in the diagnosis of hydatid disease was compared with that of the Casoni intradermal (ID) test in 47 patients with surgically confirmed hydatid disease and 73 controls. When an antigen prepared from whole bovine hydatid fluid was used in the ID test, the reaction was positive in only 32 patients, whereas the ID test was positive in 38 patients when an antigen prepared from boiled hydatid fluid was used. The IEP test was positive in 37 of the 47 patients. Regardless of cyst localization, the lowest diagnostic sensitivity was observed in patients whose cysts were intact and of the hyaline type, whereas recently broken cysts were associated with the most consistently detectable immune response. Five patients were negative to both the IEP and ID tests. Comparing the IEP test and the ID test (using the boiled antigen), 33 patients were positive in both tests; 5 patients were positive in the ID test and negative in the IEP test, and 4 were positive in the IEP test and negative in the ID test. Of the 30 controls who had other diseases, 3 gave positive reactions with both antigens in the ID test, whereas none of the 43 normal controls gave a false-positive result. One patient with hydatid cyst developed an allergic reaction 20 min after inoculation with both antigen solutions in the ID test. Until more specific antigens are available, there appears to be little value in using the ID test when the more specific serological techniques are available.

8403 SEROLOGIC EVIDENCE OF THE POSTOPERATIVE PERSISTENCE OF HYDATID CYSTS IN MAN. (Eng.) Matossian, R. M.; Araj, G. F. (Dept. Bacteriology, Virology, American Univ. Beirut, Beirut, Lebanon). *J. Hyg. (Camb.)* 75(3):333-340; 1975.

The sensitivity of the hemagglutination (HA), complement fixation (CF), and indirect fluorescent antibody (IFA) tests in the diagnosis of primary and recurrent hydatid disease was studied in 80 patients with primary hydatid cysts, 62 patients previously operated upon for hydatid cysts (32 with no present cysts, 30 with recurrent disease), and 100 control subjects without hydatid disease. Among 50 healthy controls, all tests were negative; in the remaining 50 controls having other diseases, the HA, CF, and IFA tests were positive in 0%, 6%, and 12%, resp. The percentages of positive HA, CF, and IFA tests among 50 patients with primary hepatic hydatid cysts were 90, 80, and 96%, resp. Among 25 patients with primary pulmonary hydatid cysts, the percentages were 64, 60, and 68%, resp. Among the five primary hydatid cyst patients whose cysts occurred in other organs, the results were positive in all three tests in all cases. In the 32 patients with previous, but not recurrent disease, the HA, CF, and IFA tests were positive in 29%, 6%, and 28%, resp., suggesting that in postoperative patients, a negative CF test may indicate a better prognosis than the HA and IFA tests. In the 30 patients with recurrent disease, the percentages of positive reactions in the HA, CF, and IFA tests were 100, 97, and 100%, resp. The results indicate that by the simultaneous use of the HA and CF tests, it is possible to appraise the antibody globulin pattern of most patients with hydatid disease and thus establish a presumptive diagnosis or prognosis of the condition. IFA tests were not as useful in establishing the diagnosis and prognosis as originally expected.

GENERAL

Regional Enteritis

8414 ENDOSCOPIC FEATURES OF GASTRODUODENAL CROHN'S DISEASE. (Eng.) Danzi, J. T.; Farmer, R. G.; Sullivan, B. H., Jr.; Rankin, G. B. (Cleveland Clinic Foundation, 9500 Euclid Ave., Cleveland, OH 44106). *Gastroenterology* 70(1):9-13; 1976.

The clinical, roentgenographic, and endoscopic findings in 14 patients with Crohn's disease of the stomach and/or duodenum are described. Three patients had ileal and gastroduodenal Crohn's disease; nine had ileal, colonic, and gastroduodenal Crohn's disease; and two patients had only gastroduodenal Crohn's disease. The mode of clinical presentation included upper gastrointestinal tract obstruction symptoms (7 patients), epigastric pain (6 patients), and occult upper gastrointestinal bleeding (1 patient). There was good documentation of the roentgenographically observed mucosal nodularity, antral narrowing, duodenal strictures, and thickened antral folds by endoscopy. Endoscopy revealed mucosal nodularity in 13 of 14 patients, multiple aphthous-like ulcerations in 9 of 14 patients, and linear or serpiginous ulcerations in 5 of the 9 patients with aphthous-like ulceration. Other endoscopic features included thickening of the antral folds in 7 of 11 patients with gastric disease, antral narrowing in 3 of 7 patients with gastric and duodenal disease, and duodenal stricture in 5 of 10 patients with duodenal disease. Endoscopic biopsy showed granulomatous inflammation in two of nine cases and chronic inflammation without evidence of noncaseating granuloma in seven cases. The diagnosis of Crohn's disease can be achieved by combining clinical, roentgenographic, and endoscopic features.

8415 CROHN'S DISEASE OF THE COLON. V. RETROPERITONEAL LUMBOCRURAL ABSCESS IN CROHN'S DISEASE INVOLVING THE COLON. (Eng.) Greenstein, A. J.; Dreiling, D. A.; Aufses, A. H., Jr. (Dept. Surgery, Mount Sinai Sch. Medicine, City Univ. New York, 100th St. and Fifth Ave., New York, NY 10029). *Am. J. Gastroenterol.* 64(4):306-318; 1975.

Of 231 patients with Crohn's colitis or ileocolitis, 12 (aged 11-36 yr), all within the group of 175 ileocolitis patients, developed a retroperitoneal lumbocrural abscess. At least 4 abscesses originated in the fistulous tracts of the colon, and 11 developed spontaneously as the first major complication of ileocolitis. The incidence of diarrhea, pain, weight loss, and toxemia did not differ significantly from the 219 remaining patients (controls). There was a significant difference ($p<0.005$) in clinical features: thigh pain, hip flexion, hydronephrosis and hydroureter, and abdominal mass. The number of internal and external fistulas was significantly higher ($p<0.005$) in patients with abscess (75% and 41%, resp.) than in controls (31% and 11%). Paracolic extraperitoneal aggregates of gas extending into the psoas sheath, paracolic area or thigh were noted radiologically in four patients. All the patients ultimately required some form of surgery, such as drainage, diversion, or resection. Although 4 required only a single procedure and 10 are now in relatively good health, 8 patients have been subjected to from two to six major procedures to deal with the abscess, its sequelae, and the natural progression of the disease.

8416 PROCTOCOLITIS AND CROHN'S DISEASE OF THE COLON: A COMPARISON OF THE CLINICAL COURSE. (Eng.) Lennard-Jones, J. E.; Ritchie, J. K.; Zohrab, W. J. (St. Mark's Hosp., London, England). *Scand. J. Gastroenterol.* 1(2):477-482; 1976.

The clinical course of 130 patients with proctocolitis (PC) and 58 patients with Crohn's colitis (CC) was followed from the time of their first hospital admission during the decade 1963-1972. More PC patients (68%) were admitted with acute symptoms than those with CC (41%). Operation rates were similar, but urgent surgery was required more frequently in the PC group ($p<0.025$). After the first 2 yr, however, this rate in PC patients was low, but among CC patients it increased until the sixth year. The chance of requiring operation among CC patients was 72% within 6 yr of first admission compared with 44% among PC patients. Local surgery for anal lesions was more common in CC patients. The only significant difference in overall mortality ($p<0.01$) was during the first year, in which seven PC patients died but all the CC patients survived. Thereafter, the rates were similar, and the probability of surviving 8 yr was 81% in PC patients and 73% in CC patients. This study suggests that proctocolitis has an acute and potentially dangerous onset, but the illness appears to become less severe after survival for 1 yr; Crohn's colitis tends to be more chronic and progressive over several years, with a greater need for surgical treatment and a greater tendency to anal complications.

8417 COLONIC AND INFLAMMATORY BOWEL DISEASES. (Eng.) Janowitz, H. D.; Sachar, D. B.; Kern, F.; Kirsner, J.; Mendeloff, A.; Schuster, M.; Thayer, W.; *et al.* (Work group VIII, American Gastroenterological Association, Baltimore, MD). *Gastroenterology* 69(5):1140-1150; 1975.

8418 GRANULOMATOUS DISEASE OF THE INTESTINAL TRACT (CROHN'S DISEASE). (Eng.) Marshak, R. H. (Mount Sinai Sch. Medicine, New York, NY). *Radiology* 114(1):3-22; 1975.

8419 CROHN'S DISEASE IN THREE SUDANESE PATIENTS. (Eng.) El Masri, S. H.; Satir, A. A. (Dept. Surgery, Univ. Khartoum, Khartoum, Sudan). *East Afr. Med. J.* 52(5):284-293; 1975.

8420 NEW OBSERVATIONS IN CROHN'S DISEASE. (Eng.) Janowitz, H. D.; Sachar, D. B. (Mount Sinai Sch. Medicine, New York, NY 10029). *Annu. Rev. Med.* 27:269-285; 1976.

8421 UNUSUAL COMPLICATIONS OF REGIONAL ENTERITIS: DUODENOBILIARY FISTULA AND HEPATIC ABSCESS. (Eng.) Zarnow, H.; Grant, T. H.; Spellberg, M.; Levin, B. (St. Francis Hosp., 929 N. St. Francis, Wichita, KS 67214). *JAMA* 235(17):1880-1881; 1976.

8422 THE DIFFERENTIAL DIAGNOSIS OF CROHN'S DISEASE BY CONVENTIONAL RADIOLOGICAL EXAMINATION. (Eng.) Zissu J.; Filippini, L. (Kantonsspital, CH-6004 Lucerne, Switzerland). *Radiol. Clin.* 44:557-570; 1975.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism an Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1978.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

8423 QUANTITATIVE STUDY OF DUODENAL SEROTONIN-PRODUCING CELLS IN RABBIT FETUS. (Fre.) L'Hermite, A.; Lefranc, G.; Pradal, G.; Andre, M. J.; Tusques, J. (Laboratoire d'Histologie et Embryologie, Faculte de Medecine, 1 rue Gaston Veil, 44035 Nantes Cedex, France). *C. R. Soc. Biol.* 169(4):1034-1040; 1975.

The number and distribution of duodenal serotonin-producing cells were determined in fetal rabbits. Serial sections (total, 400) of duodenum both proximal and distal to the pylorus were prepared by Falck's method from 21-, 22-, 23-, and 25-day-old fetuses. The earliest serotonin cells (SC) appeared around the 20th day of gestation. By 22 days, their number was appreciable, and they increased markedly between days 23 and 25. In general, the number of cells varied directly with weight and age. At 21-22 days, the number of fluorescent cells at the pylorus level was lowest, increasing gradually distally. By day 22, the cell pattern was either relatively constant, before it began oscillating regularly, or there was neither stabilization nor regular variation. The relatively constant pattern is assumed to be the duodenal rudiment. Mucosal samples taken from the same site in different fetuses of the same age and weight never showed the same concentration of serotoninergic cells. Two consecutive mucosal segments from the same fetus were more comparable; however, there was no significance between the proximal and distal segments.

8424 REGULAR STRUCTURES IN UNIT MEMBRANES. II. MORPHOLOGICAL AND BIOCHEMICAL CHARACTERIZATION OF TWO WATER-SOLUBLE MEMBRANE PROTEINS ISOLATED FROM THE SUCKLING RAT ILEUM. (Eng.) Jakoi, E. R.; Zampighi, G.; Robertson, J. D. (Dept. Anatomy, Duke Univ., Durham, NC 27710). *J. Cell Biol.* 70(1):97-111; 1976.

Specialized plasma membranes from the endocytic complex of ileal epithelial cells of suckling Sprague-Dawley rats were isolated by differential flotation to determine their morphological and biochemical characteristics. Homogenates of epithelial scrapings from the ileum were centrifuged on a sucrose step gradient to isolate the endocytic membrane. The purity of the membrane fractions was assessed by electron microscopy, using thin sectioning and negative stain techniques. In cross sections at higher power, the membranes had a characteristic trilaminar structure about 8-nm thick, with one leaflet decorated with discrete particles about 7.5 nm in diameter and spaced about 14.5 nm apart. Low specific activities of α-galactosidase and β-glucuronidase (β-Glu) were detected in the isolated membrane fractions, as well as in the whole homogenate. A low specific activity of acid phosphatase was found, indicating a 33% enrichment of this enzyme in these fractions. Some β-Gal activity was also present at 35% of its total specific activity in the whole homogenate. The predominant disaccharidase activity associated with the isolated membranes was *n*-acetyl-β-glucosaminidase (NAG); approximately 98% of specific activity in the total homogenate was retained in this fraction. The particulate coating was released from the membrane surfaces by 10 mM $CaCl_2$ and recovered free of membranes after dialysis against 5 mM EGTA and high speed centrifugation. Two proteins were found by gel filtration to be in the supernatant: NAG and a filamentous protein, which attached *n*-acetylglucosaminidase to the membrane surface, thereby providing bidirectionality to the array of enzyme. The results suggest that the membranes of the endocytic complex are sites for the extracellular digestion of the carbohydrate moieties in the maternal milk.

8425 LIGHT MICROSCOPY, ELECTRON MICROSCOPY AND CLINICAL FINDINGS IN ORTHOTOPIC ALLOGENIC PORCINE LIVER HOMOGRAFTS. (Ger.) Mahnke, P.-F.; Cossel, L.; Schwarzer, R.; Otto, U. (Pathologisches Institut, Karl-Marx-Universitat, 701 Leipzig, Liebigstrasse 20, E. Germany). *Zentralbl. Allg. Pathol.* 119(6):495-526; 1975.

A uniform conception of pathogenetic events in porcine liver homografts was developed from macroscopic, light and electron microscopic, clinical, and paraclinical data harvested from 39 transplant experiences. The total ischemia time for the transplanted liver was 3-3.5 hr. The liver was placed in an orthotopic position in the hepatectomized host, and arterialization was followed by direct anastomosis with the common hepatic artery. The anastomotic sequence included suprahepatic vena cava, hepatic artery, portal vein, subhepatic vena cava, and sutured cholecystoduodenostomy. Survival time varied from a few hours to 179 days; 15 patients died within 24 hr. There was a 100% leukopenia immediately postoperatively, followed by a 60% leukocytosis up to day 15; a gradual leukopenia and erythrocytopenia began at weeks 16 or 17. Elevated SGOT and LDH were normalized in 1 week. Serum bilirubin changed little. The principal causes of death were hemorrhagic diathesis (15), postoperative gastric ulcer with massive hemorrhage (12), pneumonia (5), and cholangitis (2). The livers were unexceptional in 14 cases; perfusion disturbances, including infarction, occurred in 12 instances, fatty liver in 6, icterus in 5, fibrosis or cirrhosis in 2, and viral hepatitis in 10. Vacuolization, hyaline deposition, fibrin precipitation, and defective hepatocyte membranes (abnormally high permeability) were identified microscopically. The smooth endoplasmic reticulum was especially prominent. Organelle modification was attributed to adaptive hypertrophy (metabolic activation), which, in conjunction with altered permeability, can progress to partial peripheral lysis and total lytic necrosis. These are probably signs of late rejection by sensitized host lymphocytes. There was also a strong suspicion that donor Kupffer cells attack host lymphocytes. The clinically and functionally compensated late phase presented a histological picture resembling chronic active hepatitis.

8426 HISTOCHEMICAL STUDIES ON THE ALBINO RAT PANCREAS IN DIFFERENT PERIODS FOLLOWING VAGOTOMY AND SIMULTANEOUS PYLOROMYOTOMY. (Eng.)

Wesolowski, H.; Snop, S. (Pomeranian Medical Acad., Al, Powstancow 72, 70-111 Szczecin, Poland). *Folia Histochem. Cytochem. (Krakow)* 13(1/2):85-92; 1975.

The effect of complete subphrenic vagotomy and simultaneous pyloromyotomy on the morphological state and activities of some intracellular enzymes of the albino rat was studied histochemically. Within the first weeks after vagotomy, the pancreatic acini diminished in size, and the β-cells in the islets of Langerhans became edematous. In the acini, the activities of succinate dehydrogenase, cytochrome oxidase, "AS" naphthol acetate esterase, and glucose-6-phosphatase declined, but the reactions for beta-glucuronidase and aryl sulfatase showed intensifications and polymorphic behavior both in acinar and in islet cells. The islet cells, particularly the β-cells, simultaneously revealed enhanced activities of succinate dehydrogenase, cytochrome oxidase, β-glucuronidase, and aryl sulfatase and an entire disappearance of the reaction for glucose-6-phosphatase. The α-cells increased their "AS" naphthol acetate esterase activity. Five weeks after vagotomy, morphological and enzymatic changes in the acini and islet cells were negligible, and after 5 and 9 months, no differences were noted between the vagotomized rats and the control animals. Data from other studies support the view that the activity changes observed in the present study may be due to a temporary degradation of cell structures following the cutting of the vagi. Resumption of a normal enzymatic activity these cells within 5 months of vagotomy supports this view.

8427 EXPERIMENTAL XENOGENIC IMMUNE PANCREATITIS. 1. HISTOLOGICAL FINDINGS IN THE MOUSE EXOCRINE PANCREAS AFTER TREATMENT WITH ANTI-MOUSE PANCREAS RABBIT SERUM. (Ger.)

Nizze, H. (Institut fur Allgemeine und Spezielle Pathologie, Universitat Rostock, DDR-25 Rostock 1, Strempelstrasse 14, E. Germany). *Exp. Pathol. (Jena)* 11(1/2):10-20; 1975.

The morphological alteration in exocrine mouse pancreas (MP) after challenge by xenogenic immune MP antiserum is analyzed. The test groups included 35 mice with anti-MP rabbit serum (group A), 14 with normal rabbit serum (group B), 16 with physiological saline (group C), and 6 untreated controls. The test groups received 1, 3, 5, 9, 17, or 33 injections, i.p., of 0.3 ml serum or saline for 0, 1, 2, 4, 6, 8, or 16 days. In group A, the MP was hyperemic and edematous in 3 hr; by day 33, it was smaller, pale, and resistant. The edema was inter- and intralobular and periacinar, with multiple acinar cell necroses by days 2-3 leading to focal immobilization of entire lobules. The cytoplasm was finely vacuolated and hypertrophic, the nucleus was relatively unaffected. Infiltration of eosinophils and neutrophils preceded that of histiocytes, lymphocytes, and later, plasma cell invasion in affected acinar fields. By day 17, there was dense stromal proliferation in the parenchyma, with evidence of ductal regeneration. By day 28 after the final injection, the edema and acinar necroses had disappeared, with reduced interstitial fibrosis in the submesothelium and small, local periductal, interlobular, and periinsular lymphocyte clusters. The chronic sclerosing pancreatitis changed into focal perivascular lipomatosis in 4 weeks in mice treated more than 16 days. Group B mice experienced only local interstitial edema qualitatively similar to that in group A, but quantitatively negligible in comparison. Group C showed minute alterations in subperitoneal stroma. The acinar necroses are expressions of cytotoxic immune aggression. The cellular response is both a resorptive reaction to the cytotoxic damage and an immunologic or delayed-type reaction of serum sickness, following repeated inoc lation.

8428 ULTRASTRUCTURAL ASPECTS IN THE PATHOGENESIS OF DEOXYCHOLATE PANCREATITIS. (Ger.)

Backwinkel, K. P.; Schriewer, H.; Rauen, H. M.; Themann, H. (Medizinische Klinik und Poliklinik der Universitat, D-4400 Munster/Westfalen, Westring 3, W. Germany). *Res. Exp. Med. (Berl.)* 166(1):43-52; 1975.

Modifications of the exocrine pancreas after deoxycholate (DOC) administration were studied electron microscopically. DOC (0.7 ml) was administered i.p. to 55 male rats, who were then sacrificed at 0 to 54 hr. Focal degeneration in the mitochondria and endoplasmic reticulum (ER) occurred in 2-4 hr, with the presence of osmiophilic fragments. By 12 hr, the osmiophilic deposits had increased, especia ly between the ER membranes. The accumulations became subsequently confluent, forming structures that were either empty or filled with membrane fragments. Later, the empty vacuoles were filled with amorphous material of varying electron densities. Zymogen granulation was apparent in the larger foci At 54 hr, the affected cells showed a structure-fre thickened cytoplasm in which collapsed rough ER was visible. Zymogen fusion led to inclusion body form tion. In addition to prominent interstitial edema, a neutrophil excess was found. However, many exten ed tissue sections remained unaltered by DOC. Base on comparable liver studies, a disturbance to the membrane lipid metabolism is proposed. DOC reflux in the pancreatic duct could explain the origin of acute pancreatitis.

36 SMALL INTESTINAL PERMEABILITY. I. EF-
FECTS OF ISCHAEMIA AND EXPOSURE TO ACETYL
LICYLATE. (Eng.) Kingham, J. G. C.; Whorwell,
J.; Loehry, C. A. (Royal Victoria Hosp., Bourne-
uth, England). *Gut* 17(5):354-361, 1976.

study the permeability characteristics of the
all intestinal epithelial cell layer, the perme-
ility of the small intestinal mucosa of female
bbits was estimated using a perfusion technique
ter the epithelial layer was damaged either by 2
of ischemia or by exposure to acetyl salicylate.
chemia significantly increased intestinal perme-
ility to povidone, insulin, inulin, vitamin B_{12},
d creatinine (by 500, 470, 510, and 180%, resp.),
t was without effect on intestinal permeability
urea. For substances greater in size than cre-
inine, there was a constant increase in clearance
ter ischemia; thus, for larger molecules, perme-
ility was increased but selectivity was unaltered.
posure to un-ionized acetyl salicylate (pH 2.6,
min) also increased the intestinal permeability
povidone, inulin, vitamin B_{12}, and creatinine
y 740, 720, 810, and 170%, resp.). Both proce-
res produced a derangement of the epithelial cell
yer of the villous tips, without damage to the
ithelial basement membrane or subepithelial struc-
res. It is concluded that the epithelial cell
yer is purely rate-limiting, with no selective
nction, and that the role of selectivity must be
cribed to either or both of the other mucosal bar-
ers, the capillary and the epithelial basement
mbrane.

8437 INTESTINAL CALCIUM TRANSPORT: PARATHYROID HORMONE AND ADAPTATION TO DIETARY CALCIUM. (Eng.) Ribovich, M. L.; DeLuca, H. F. (Dept. Biochemistry, Coll. Agricultural Life Sciences, Univ. Wisconsin-Madison, Madison, WI 53706). *Arch. Biochem. Biophys.* 175(1):256-261; 1976.

The relation between the parathyroid hormone system and the adaptation of intestinal Ca absorption to dietary Ca was investigated in male Holtzman rats. Sham-operated rats maintained for 12 days on a low-calcium diet (0.1%) and given 1,25-dihydroxyvitamin D_3 (250 ng, p.o.) daily had a significantly higher mean intestinal calcium transport ratio (serosal ^{45}Ca/mucosal ^{45}Ca=9.5) than rats on either a vitamin D-supplemental normal calcium diet (0.47% Ca, transport ratio=5.2) or a vitamin D-supplemented high calcium diet (1.2% Ca, transport ratio=5.5). This effect was eliminated in another group of rats 4 days after thyroparathyroidectomy; the thyroparathyroidectomized animals on the low calcium diet had a transport ratio (4.9) that was significantly lower than that of sham-operated rats on a low calcium diet. Thyroparathyoidectomy had no effect on calcium transport of rats on either the normal or high calcium diet. The chronic administration of a constant exogenous source of parathyroid hormone (40 U/8 hr/100 g parathyroid extract) to thyroparathyroidectomized rats supplemented with vitamin D resulted in high rates of intestinal calcium transport in rats fed diets containing 0.02% calcium (transport ratio =6.1) or 2.0% calcium (6.7). Since 1,25-dihydroxyvitamin D_3 supplementation eliminates adaptation of intestinal calcium transport to a low calcium diet in a similar manner, these results support the suggestion that the parathyroid glands mediate intestinal adaptation by the stimulation of 1,25-dihydroxyvitamin D_3 biosynthesis by secreted parathyroid hormone.

8438 Na^+-K^+-ACTIVATED ADENOSINE TRIPHOSPHATASE AND INTESTINAL ELECTROLYTE TRANSPORT: EFFECT OF ADRENAL STEROIDS. (Eng.) Charney, A. N.; Kinsey, M. D.; Myers, L.; Giannella, R. A.; Gots, R. E. (Dept. Gastroenterology, Walter Reed Army Medical Center, Washington, DC 20012). *J. Clin. Invest.* 56(3):653-660; 1975.

To help delineate the role of adrenal steroids in intestinal transport, changes in intestinal electrolyte and water transport were induced in male Walter Reed rats by injecting methylprednisolone (3 mg/100 g) or deoxycorticosterone (DOCA, 0.5 mg/100 g) s.c. daily for 3 days. Untreated normal litter mates served as controls. Twenty-four hours after the last steroid injection, the small intestine and colon of the experimental rats were perfused *in vivo*, and mucosa specimens from the jejunum, ileum, and colon were assayed for adenosine triphosphatase (ATPase) and adenylate cyclase activity. Methyl-prednisolone increased sodium and water absorption, and potassium secretion in the jejunum, ileum, and colon. It resulted in mean transmural electrical potential differences of 10.1, 16.5, and 43.9 mV in the jejunum, ileum, and colon, resp., which had been perfused with isotonic saline containing 56 mM glucose; these values were significantly increased over values in control intestine (6.8, 4.2, and 14.6 for jejunum, ileum, and colon, resp.), which had also been perfused with glucose. These changes were accompanied by marked increases in Na-K-ATPase activity in each intestinal segment. Examination of isolated epithelial cells demonstrated that the jejunal and ileal increase in Na-K-ATPase occurred in both the villus tip and crypt areas. The mean control values in the jejunum were 74.7 and 33.7 μmol Pi/mg protein/hr for the villus tip and crypt, resp.; in the ileum, they were 60.2 and 29.7 μmol Pi/mg protein, resp. In the jejunum of methylprednisolone-treated animals, the values were 108.0 and 52.1 μmol Pi/mg protein/hr for villus tip and crypt, resp., and 101.0 and 59.6 μmol Pi/mg/hr, resp., in the ileum. The time-courses of the ileal enzyme and transport changes were identical. Permeability, Mg-ATPase, and adenylate cyclase activities were unchanged by methylprednisolone. DOCA increased sodium and water absorption (approximately 100%), potassium secretion, and Na-K-ATPase activity in the colon only. The transmural electrical potential difference was significantly higher in only the colon (38.7 mV) after DOCA treatment and glucose perfusion, in comparison with that in controls (14.6 mV). Colonic Mg-ATPase and adenylate cyclase activities, jejunal and ileal enzyme activity, electrolyte transport, and permeability were unchanged by DOCA. Methylprednisolone and DOCA were not additive in their effect on colonic Na-K-ATPase activity. The two substances increased electrolyte and water transport and Na-K-ATPase activity concomitantly in specific segments of small intestine and colon. These data are consistent with an important role for Na-K-ATPase in intestinal electrolyte and water transport.

8439 ENTERAL SODIUM AND FLUID TRANSPORT BEFORE AND AFTER RADIATION EXPOSURE. PHYSIOLOGICAL INVESTIGATIONS ON AWAKE RATS. I. UPPER SMALL INTESTINE. (Ger.) Herzer, R. (Strahleninstitut der Universitat Tubingen, 7400 Tubingen, W. Germany) *Strahlentherapie* 147(5):531-543; 1974.

The effect of gamma radiation on water and sodium transport as a function of dose level, postexposure terval, and osmolarity of the perfusion solution and bowel segment was studied. Awake, nonnarcotized Sprague Dawley rats were laparotomized, and a 10-cm loop of upper jejunum was mobilized for extracorporeal perfusion. Whole body radiation was performed at 500 and 1,000 rads. Perfusion fluids included water (hypotonic), 0.9% NaCl (isotonic), and 1.8% NaCl (hypertonic) and were administered at 12-16 hr and 36-40 hr after radiation. Preradiation perfusion with water was resorptive only. Postradiation, with increasing dose and time, there was a continuous decrease in net resorbed volume to half the normal. Isotonic transport was also resorptive, but of smaller magnitude. Postradiation, the decrease was proportional to dose and time: at 36-40 hr after 1,000 rads, the flow was one-quarter of the initial level. Radiation also reduced the compensatory intraluminal sodium transport in both the isotonic and hypotonic cases. The hypertonic flow was decreased by half after radiation, and the intraintestinal sodium accumulation fell 2.38 μEq/cm^2 36-40 hr after 1,000 rads. The isolated influence of dose and interval and their reciprocity showed a predominance of the time factor. in contras to the dose, in the hypo- and isotonic range.

8440 Na^+ AND Cl^- TRANSEPITHELIAL ROUTES IN RABBIT GALLBLADDER: TRACER ANALYSIS OF THE TRANSPORTS. (Eng.) Cremaschi, D.; Henin, S. (Istituto di Fisiologia Generale, Universita degli Studi di Milano, Via Mangiagalli 32, I-20 133 Milan, Italy *Pfluegers Arch.* 361(1):33-41; 1975.

Na^+ and Cl^- transport were studied in the rabbit gallbladder by chemical and radiochemical methods. Na^+ influx through the luminal barrier over 45 sec was reduced from a control level of 20.8 μmol/cm^2/hr to a level of 12.7 μmol/cm^2/hr in Cl^--free bathing solution, and Cl^- transport was reduced from a control level of 23.0 μmol/cm^2/hr to 10.9 μmol/cm^2/hr in Na^+-free solution. Further experiments revealed that influx was dependent on both luminal and cellular ion concentrations. Cellular Cl^- labeling with $^{36}Cl^-$ (1-hr incubation) was almost completely abolished in Na^+-free bathing solution, but cellular Na^+ labeling with $^{22}Na^+$ in the lumen did not change in a Cl^--free bathing solution. Cellular Na^+ and Cl^- labeling through the basolateral membrane wa negligible; some Cl^- labeling was obtained only when the intracellular electrical potential was reduced. Fluid transport was completely abolished when the ma nion in the incubating solution was SO_4^{2-}, i.e., an nion that does not enter the cell, but can diffuse nrough the epithelium via an extracelluar pathway. ne results suggest that Na^+ and Cl^- cotransport takes lace through the cell luminal barrier and that Na^+ s actively extruded through the basolateral membrane.

441 ION TRANSPORT BY RABBIT COLON. I. ACTIVE AND PASSIVE COMPONENTS. (Eng.) Frizzell, . A.; Koch, M. J.; Schultz, S. G. (Univ. Pittsburgh, ch. Medicine, Pittsburgh, PA 15261). *J. Membr. iol.* 27(3):297-316; 1976.

he movements of Na, Cl, and K across the rabbit escending colon were studied under short-circuit onditions, and the passive fluxes of these ions cross the epithelium were evaluated using a voltage-lamp procedure. The effects of ion replacement, uabain, amiloride, and cyclic AMP were also studied. he colon, stripped of the muscularis externa, bsorbed Na and Cl under short-circuit conditions, ut net K transport was not observed. The colon xhibited a residual ion flux, and the magnitude as approximately equal to the rate of active Cl bsorption [short-circuit current=2.8 μEq/cm^2; et Na transport=3.0 μEq/cm^2]. The short-circuit urrent was abolished in Na-free solutions, suggestng that it is determined solely by the rate of ctive Na transport; the results of further ion eplacement studies and treatment with ouabain or miloride supported this conclusion and suggested hat the net movements of Cl and HCO_3 are mediated y a Na-independent, electrically-neutral, anion xchange process. Cyclic AMP stimulated an elecrogenic Cl secretion, abolished HCO_3 secretion, ut did not affect the rate of Na absorption nder short-circuit conditions. Studies of he effect of transepithelial potential differnce on the serosa-to-mucosa fluxes of Na, K, and l suggested that the total fluxes of Na and K, and ne-third of Cl may be attributed to ionic diffusion. he permeabilities of the passive conductance pathay(s) were such that the ratio of the permeabiliies of K:Na:Cl were 1.0:0.07:0.11. Electrolyte ransport by *in vitro* rabbit colon closely resembles hat reported for *in vivo* studies of mammalian colon nd may serve as a useful model for the further tudy of colonic ion transport mechanisms.

442 RENAL CONTROL OF INTESTINAL SODIUM AND WATER TRANSPORT IN THE DOG. (Eng.) Nizet, A.; obin, M.; Merchie, G. (Hopital de Baviere, Boulevard e la Constitution, 66, B-4020 Liege, Belgium). *fluegers Arch.* 364(1):59-64; 1976.

xperiments were carried out in dogs to determine hether the impairment of jejunal sodium and water bsorption by i.v. saline infusion depends on the revious dietary sodium intake and whether the sensitivity of the jejunum to this infusion is modulated y a humoral material released into the blood by the idney. Twenty dogs received a sodium-depleted diet (0.15 mEq Na/kg/day) and 10 dogs received a sodium-nriched diet (24 mEq/kg/day) for 2 weeks. While the net intestinal transport was reduced after the saline infusion in sodium-loaded animals, no response was observed in the dogs that had been on sodium-depleted diets, despite identical changes in arterial pressure, intravascular volume, and blood dilution indexes. When the kidneys were removed from sodium-loaded animals and transplanted to the neck vessels of the sodium-deprived dogs, the sodium and water absorption during the saline infusion was impaired. This demonstrates that the presence of a humoral message of renal origin in the blood is required to permit the inhibition of net transport. These experiments suggest that the kidney might modulate sodium transport in the jejunum, and perhaps elsewhere in the body, by way of an additional endocrine function.

8443 THE EFFECT OF IRON STORES ON IRON ABSORPTION IN THE RAT: THE POSSIBLE ROLE OF CIRCULATING FERRITIN. (Eng.) Greenman, J.; Jacobs, A. (Welsh Natl. Sch. Medicine, Heath Park, Cardiff, Wales). *Gut* 16(8):613-616; 1975.

The relation between Fe absorption and the body Fe stores plus the effect of elevating the serum ferritin concentration during absorption were studied in 3-month-old male Wistar rats. Storage Fe was increased by i.m. injections of 5 mg on alternate days, for a total of 5-50 mg Fe. Fourteen days after the last injection, a solution containing 5 μg of ^{59}Fe ferric ammonium sulfate was administered by stomach tube, and the total radioactivity in the rat was counted immediately 7 days later. In the second experiment, rats were perfused i.v. (for 45 min) with 0.9% sterile sodium chloride solution alone (controls) or with a solution containing 100 μg of rat ferritin. Fifteen minutes after the perfusion was begun, 1 ml of ^{59}Fe ferric ammonium sulfate solution was introduced into the gut through an intestinal cannula. At the end of the perfusion, the absorption of ^{59}Fe by the gut was estimated. In the first experiment, correlations were noted between the amount of Fe injected and serum Fe concentration ($p<0.05$) and between the former and transferrin saturation ($p<0.01$). There was no correlation between serum Fe concentration or transferrin saturation and Fe absorption. There was a significant negative correlation between the liver nonheme Fe concentration and Fe absorption ($p<0.001$). In the second experiment, there was a 100-fold increase in serum ferritin concentration and a slight increase in serum Fe concentration and transferrin saturation after ferritin perfusion. However, there was no difference in Fe absorption between the control and ferritin groups and there was no difference in the proportion of administered Fe taken up by the intestinal mucosa. These data suggest that although the amount of storage Fe regulates Fe absorption in the rat, it does not do so simply through variations in the circulating ferritin concentration.

8444 INFLUENCE OF ASPIRIN, ANTACIDS, ALCOHOL, AND BILE ACIDS ON TRANSMURAL POTENTIAL DIFFERENCE OF THE HUMAN STOMACH. (Ger.) Caspary, W. F. (Abteilung Gastroenterologie und Stoffwechselkrankheiten, Medizinische Universitatsklinik, 34 Gottingen, Humboldtalle 1, W. Germany). *Dtsch. Med. Wochenschr.* 100(23):1263-1268; 1975.

The effects of alcohol, antacids, bile acids, and aspirin on the gastric mucosal barrier of healthy persons were measured by changes in transmural potential (TMP). The test group consisted of 10 fasting young adult volunteers. Circuitry was maintained by two agar-KCl-filled tubes: one inserted intragastrically and one placed in a peripheral arm vein. The test agents, administered by gavage, included 1,000 mg aspirin (ASP), 1,000 mg antacid-aspirin (AASP), 50 ml ethyl alcohol (EA), 40 ml commercial whiskey (18 g alcohol), 250 ml commercial wine (17.5 g alcohol), a 5.5 mM bile acid mixture (4 mM taurocholic, 1 mM chenodeoxycholic, 0.5 mM deoxycholic acid), and 640 mg of citrate-buffered ASP. ASP elicited a massive drop in TMP beginning at 1 min and peaking at 10 min. Simultaneous AASP significantly weakened the voltage drop. There was no change in TMP after buffered ASP. Administration of 10 ml antacid (Gelusil) alone increased the intragastric pH. EA significantly lowered the TMP, compatible with its stimulation of hydrogen ion back-diffusion. Both whiskey and wine also elicited TMP decreases; initial TMP was not restored even after 40 min. The bile acid mixture and ox bile induced a TMP drop. TMP is concluded to be a simple diagnostic procedure for assaying functional mucosal changes.

8445 THE SPECIFICITY OF BILE SALTS IN THE INTESTINAL ABSORPTION OF MICELLAR CHOLESTEROL IN THE RAT.

(Eng.) Watt, S. M.; Simmonds, W. J. (Dept. Physiology, Univ. Western Australia, Nedlands 6009, Western Australia). *Clin. Exp. Pharmacol. Physiol.* 3(4):305-322; 1976.

The importance of solubilization in cholesterol absorption and the effects of different bile salts on the mucosal metabolism and lymphatic output of cholesterol were investigated using two different *in vivo* techniques. Bile diverted lymph fistula Wistar rats were infused intraduodenally at a steady rate with a constant lipid mixture containing (4-^{14}C)-cholesterol, (9,10-$^{3}H_2$)-oleic acid and monoolein. The lipids were completely solubilized in either bile salts or a non-toxic non-ionic detergent, Pluronic F68. Labeled fatty acid was efficiently absorbed from either micellar infusate, but virtually no labeled cholesterol appeared in the lymph in the absence of bile salts. Short-term perfusions of the intestine of anesthetized rats with the same micellar perfusates showed approximately 20% of the labeled cholesterol in the mucosa after 30 min perfusion with the bile salt micellar solutions. When the nonionic micelles were used, no isotopic cholesterol left the lumen. Mucosal uptake of labeled cholesterol was linearly dependent on the concentration of solubilized cholesterol in the perfusate and was not dependent on the bile salt concentration. After 30 min, the total amount of perfused isotopic cholesterol was recovered from either the lumen or the mucosa, but some fatty acid appeared to have been transported away from the mucosa by this time. The initial rate of mucosal uptake of labeled cholesterol was similar from micellar perfusates using either taurocholate, taurodeoxycholate, or taurofusidate. In contrast, after 8 hr of infusion, lymphatic output of labeled cholesterol was markedly greater with taurocholate. The increased lymph output with taurocholate was associated with an increase in the esterified fraction of both labeled and unlabeled cholesterol. Fatty acid was absorbed and esterified equally from all three types of perfusate. These results suggest that for the first step in cholesterol absorption, uptake from the lumen, solubilization by a planar detergent is essential. After uptake, the more rapid transfer of cholesterol to lymph in the presence of trihydroxy bile acids appears to be related to a more efficient esterification of cholestero but not to a more efficient resynthesis of triglyceride.

8446 THE BIGUANIDE INHIBITION OF D-GLUCOSE TRANSPORT IN MEMBRANE VESICLES FROM SMALL INTESTINAL BRUSH BORDERS.

(Eng.) Kessler, M.; Meier, W.; Storelli, C.; Semenza, G. (Laboratorium fur Biochemie der ETH-Zurich, Universitatstrasse 16, CH-8006 Zurich, Switzerland). *Biochim. Biophys. Acta* 413(3):444-452; 1975.

The biguanide inhibition of D-glucose transport in membrane vesicles from small intestinal brush borders was investigated in the rabbit to determine the effect of Na$^+$ on the uptake. Tissues were homogenized in hypotonic medium. After addition of Ca^{2+}, the brush border vesicles were prepared by differential centrifugation. The vesicles had undetectable levels of cytochrome oxidase, (Na$^+$ + K$^+$)-ATPase and nucleic acids, and had a sucrase specific activity o 1.4 U/mg protein. Uptake of labeled sugars was measured at 20 C in *N*-2-hydroxyethylpiperazine-*N'*-2-ethanesulfonic (HEPES) Tris buffer, pH 7.5. Concentrated D-glucose uptake was inhibited by 2.5 mM phenethylbiguanide more at low than at high external bulk concentrations of NaCl (100 mM NaCl, 25 mM NaCl + 75 mM choline chloride, and 10 mM NaCl + 90 mM choline chloride). Increased bulk concentrations of NaCl counteracted the biguanide-induced inhibition. The D-glucose uptake in 25 mM NaCl + biguanide approached that in 10 mM NaCl without biguanide. At constant Na$^+$ and biguanide concentrations, increasing the ionic strength (from 25 mM NaCl + 75 mM choline chloride to 25 mM NaCl alone) reduced inhibition by biguanides. Equilibrative D-glucose uptake was inhibited by biguanides, and the inhibition was dependent on the concentration of NaCl. The uptakes of other sugars (D-fructose and L-glucose), which are Na-independent, were not affected by biguanides. The effect of biguanides on D-glucose uptake in brush border vesicles is within the framework of the cotransport theory of Na activation of glucose/galactose transport across the brush border pole of small intestinal cells.

8447 THE ACTIVITY OF SOME INTESTINAL MUCOSAL ENZYMES IN THE ABSORPTION OF THIAMINE.

(Rus.) Kiriliuk, A. G. (Kiev Medical Inst., Kiev, USSR). *Vopr. Pitan.* (2):11-15; 1976.

Five-centimeter segments from the small intestine

male albino rats were isolated using ligatures,
d the gut section was perfused with thiamine-
ntaining physiologic saline. The absorption rate
vitamin B_1 decreased from 67% when the thiamine
ncentration in the perfusate was 3.1 μM to 47%
en the concentration was 12.3 μM. The accumula-
on of the phosphorylated thiamine was accompanied
the activation of the thiaminepyrophosphatase.
sorption of the physiological amount of thiamine
.1 μM) increased activity of the $(Na^+ + K^+)$-activ-
ed ATPase; a further increase of the vitamin B_1
ncentration (up to 24.6 μM) did not change the
tivity of the enzyme. The results indicate that
tivity of the $(Na^+ + K^+)$-activated ATPase is the
miting factor in the absorption of the large doses
the thiamine.

48 EVIDENCE FOR ACTIVE TRANSPORT OF TRIPEPTIDES BY HAMSTER JEJUNUM IN VITRO. (Eng.)

dison, J. M.; Burston, D.; Payne, J. W.; Wilkinson,
; Matthews, D. M. (Westminster Medical Sch., 124
uxhall Bridge Road, London SW1V 2RH, England).
in. Sci. Mol. Med. 49(4):305-312; 1975.

e characteristics of uptake by *in vitro* hamster
junum of three poorly hydrolyzed peptides, glycyl-
rcosylsarcosine (Gly-Sar-Sar), β-alanylglycylgly-
ne (β-Ala-Gly-Gly), and glycylsarcosylsarcosyl-
rcosine (Gly-Sar-Sar-Sar), were investigated.
y-Sar-Sar was taken up by a saturable mechanism
d accumulated intact in the intracellular compart-
nt of the intestinal wall, apparently against an
ectrochemical gradient. In a representative series
incubations, the uptake of Gly-Sar-Sar (5 μmol/
) was: Gly-Sar-Sar 7.2 ± 1.2 μmol/20 min/g
itial wet weight; Gly 2.0 ± 0.41 μmol/20 min/g;
d Sar 0.39 ± 0.06 μmol/20 min/g. Its uptake was
duced by Na^+-replacement, anoxia, and metabolic
hibitors. Uptake of Gly-Sar-Sar-Sar was very
or, and it was not concentrated in the intracel-
lar fluid of the rings. Like Gly-Sar-Sar, intact
-Ala-Gly-Gly was taken up by the intestinal tissue
a substantial scale, although uptake was less
tensive than that of the former peptide. Uptake
β-Ala-Gly-Gly was not accompanied by appearance
detectable amounts of β-Ala or Gly-Gly in the
ngs or in the incubation medium, or by a measure-
le increase in Gly; no additional chromatographic
ak that might have been β-Ala-Gly was detected,
that intestinal hydrolysis of this peptide
peared to be negligible. Uptake was inhibited by
oxia, 2,4-dinitrophenol, and Na^+ replacement.
e results suggest that tripeptides, like dipep-
ides, are actively transported into the absorptive
lls of the intestinal mucosa provided that they
scape brush border hydrolysis, but that the ability
f these cells to take up peptides by an active
echanism is unlikely to extend to tetrapeptides.

449 STUDIES ON INTRACELLULAR TRANSPORT OF SECRETORY PROTEINS IN THE RAT EXOCRINE PAN-REAS. V. KINETIC STUDIES ON ACCELERATED TRANSPORT OLLOWING CAERULEIN INFUSION IN VIVO. (Eng.)

Bieger,
.; Seybold, J.; Kern, H. F. (Dept. Anatomy, Univ. Heidelberg, Heidelberg, W. Germany). *Cell Tissue Res.* 170(2):203-219; 1976.

The finding that intracellular transport of secretory proteins in the rat exocrine pancreas is accelerated by *in vivo* stimulation with a pancreatic secretagogue was further analyzed. Using a radioassay for discharge of newly synthesized proteins, the rate of release was compared in control and prestimulated lobules. In control preparations, discharge occurred with an initial lag period of 30 min and a maximum after 2 hr of incubation. After *in vivo* infusion of cerulein (5×10^{-8} g/hr) for 24 hr, *in vitro* discharge started after 10 min incubation and attained a maximal rate after 1 hr. Using the same radioassay and several inhibitors of intracellular transport and granule discharge, both processes were reduced to the same extent in controls and in lobules with accelerated transport. To obtain direct evidence for the degree of acceleration of the different transport steps between rough endoplasmic reticulum, Golgi complex and zymogen granules, the respective subcellular fractions of these organelles were prepared and characterized ultrastructurally and biochemically. The rate of disappearance of newly formed proteins from rough microsomes and the appearance in smooth microsomes and zymogen granules were significantly increased after *in vivo* stimulation. The data substantiate an acceleration of the regular transport steps by the secretagogue. There was no indication that a high level of secretory activity leads to a rerouting of secretory proteins or to an omission of one of the regular steps in intracellular transport.

8450 STUDIES ON TOCOPHEROL DERIVATIVES: V. INTESTINAL ABSORPTION OF SEVERAL d,l-3,4-$^3H_2$-α-TOCOPHERYL ESTERS IN THE RAT. (Eng.)

Nakamura, T.; Aoyama, Y.; Fujita, T.; Katsui, G. (Dept. Drug Metabolism, Section Experimental Therapeutics Res., Eisai Co., Ltd., Koishikawa, Bunkyo-ku, Tokyo 112, Japan). *Lipids* 10(10):627-633; 1975.

The *in vitro* and *in vivo* absorption of d,l-3,4-$^3H_2$-α-tocopheryl esters by the intestine and lymphatics was studied using male Wistar rats. The acetate, propionate, butyrate, isobutyrate, caprylate, palmitate, acid succinate, benzoate, nicotinate, o-hydroxybenzoate, o-acetoxybenzoate, and pivalate esters were synthesized. They were incubated with rat bile pancreatic juice or with the supernatants of liver or small intestine homogenates. Hydrolysis was determined by thin-layer chromatography. In the *in vivo* experiments, thoracic-duct-fistula rats were given 1.15 μmol of labeled ester, and lymph was collected for 12 hr at hourly intervals to determine the lymphatic absorption rate. Irrespective of chain length, the straight chain esters were hydrolyzed equally in bile and pancreatic juice. The branched chain esters were hydrolyzed at a much slower rate, and the rates of the aromatic esters were minimal. In both bile and pancreatic juice and the supernatants, extensively branched esters such as pivalate resisted hydrolysis. In the supernatants, the long-chain fatty acid esters and aromatic esters were hydrolyzed very slowly. The rate decreased in the following order: acetate, propionate, butyrate, acid succinate, isobutyrate, caprylate, palmitate, and the aromatic esters. In the *in vivo* experiments, lymphatic absorption was highest with acetate and palmitate, followed by nicotinate, acid succinate, pivalate, and o-hydroxybenzoate. There was little correlation between lymph volume and the appearance of radioactivity in the lymph. Rats fed acetate, palmitate, and acid succinate esters absorbed the vitamin as α-tocopherol, but the pivalate ester appeared in the lymph predominantly unchanged. These data suggest that hydrolysis of α-tocopheryl esters is not a prerequisite for intestinal absorption; they also demonstrate a close correlation between the intestinal hydrolysis of these esters *in vitro* and their absorption into the lymph *in vivo*.

54 QUANTITATION OF PHARYNGEAL MOTOR FUNCTION
IN NORMAL HUMAN SUBJECTS. (Eng.) Dodds,
J.; Hogan, W. J.; Lydon, S. B.; Stewart, E. T.;
f, J. J.; Arndorfer, R. C. (Medical Coll. Wiscon-
, Milwaukee, WI 53226). *J. Appl. Physiol.* 39(4):
-696; 1975.

trumentation for recording pharyngeal pressure
nts was evaluated *in vitro* and in seven human
jects, and quantitative values for pharyngeal
istalsis were determined in normal human sub-
ts. For the *in vitro* studies, two polyvinyl
es (1.6 and 2.0 mm in diameter, resp.) were se-
ed to a strain gauge probe, filled with water,
nected to external volume-displacement trans-
ers, and inserted into a pressure wave generator.
unfixed human esophagus, obtained at autopsy,
suspended in the pressure chamber. Pressure
es simulating pharyngeal and esophageal pressure
plexes were generated, and the intraluminal re-
dings were compared with the pressure transients
hin the chamber. In the *in vivo* studies, two
es of recording assemblies were passed through
nose: a motility probe (assembly 1) and an
embly with strain gauge and open-tip catheter
ording sites (assembly 2). The resting upper
phageal sphincter pressure (UESP) and UES relax-
ion and augmentation responses to dry swallowing
e recorded. The results of the *in vitro* studies
icated that accurate quantitation of pharyngeal
or activity was not possible using a water-filled
heter system, even when high infusion rates (24
min) were used. The intraluminal strain gauge
tem, on the other hand, achieved high-fidelity
ording of simulated esophageal pressure com-
exes, although it underestimated simulated pharyn-
al pressure transients by about 10%. Quantitation
pharyngeal peristalsis using the intraluminal
ain gauge system in human subjects revealed peri-
ltic pressure amplitudes higher than those for-
ly recorded. Peristaltic amplitude averaged
ut 200 mm Hg in the hypopharynx, complexes in one
ject being as high as 600 mm Hg. A zone of rela-
ely low pressure was found in the oropharynx.
mean pharyngeal wave duration decreased progres-
ely in an aboral direction, from 1.0 to 0.3 sec,
peristaltic wave speeds ranged between 9 and 25
sec. Accurate quantitation of pharyngeal peri-
ltic variables provides the necessary basis for
characterization and assessment of pharyngeal
or disorders.

55 A NEW TECHNIQUE FOR CONTINUOUS SPHINCTER
PRESSURE MEASUREMENT. (Eng.) Dent, J.
rince Henry's Hosp., Melbourne, Victoria 3004,
stralia). *Gastroenterology* 71(2):263-267; 1976.

cm long pressure sensor that continuously meas-
es maximal lower esophageal sphincter pressure
ESP) in the face of movement of the sphincter with-
the sensor length was developed and compared with
constantly perfused side hole sensor (CPSH) in
, dog, and in a model esophageal sphincter. The
nsor consists of a 5-cm-long thin walled rubber
eeve glued along the catheter. After initial posi-
oning and anchorage, the length of the sleeve is
such that it remains in contact with the sphincter as it moves on the catheter. The sleeve is constantly perfused with water via the proximal end, and the distal end is open to vent the perfusate. Sphincter squeeze acts on the sleeve to cause increased resistance to the flow of water through it. This increased resistance is directly related to the greatest squeeze acting on the sleeve, and causes back pressure to perfusion that is measured as with CPSH. Pull-through studies in the model sphincter demonstrated that sleeve sensitivity was comparable to that of CPSH and that it was acceptably uniform along its length over the pressures tested (5-80 mm Hg). Variation of the length of the artificial sphincter from 1 to 5 cm had an insignificant effect on the pressure recorded by the sleeve compared to the side hole-recorded pressure. In 24 pull-throughs in dogs, LESP did not differ significantly for the two techniques; the mean sleeve pressure was 62.0 mm Hg and CPSH was 59.5 mm Hg. In nine human patients, sequential mean sleeve and CPSH recorded pressures were similar within each individual; the mean sleeve pressure was 10.1 mm Hg and CPSH was 9.7 mm Hg. The LES response to the swallowing of 20 ml of water was a consistent drop in pressure from 16.4 mm Hg to 2.2 mm Hg. The results demonstrate that the sleeve detects maximal LESP accurately, regardless of sphincter length, over the pressure range encountered in the lower esophageal sphincter. Continuous recording of LESP with the sleeve is unaffected by the displacement that causes serious undermeasurement with CPSH.

8466 INSULIN AND JEJUNAL ELECTRICAL ACTIVITY IN DOGS AND SHEEP. (Eng.) Bueno, L.; Ruckebusch, M. (Laboratoire de Physiologie, Ecole Nationale Veterinaire, 31076 Toulouse Cedex, France). *Am. J. Physiol.* 230(6):1538-1544; 1976.

Experiments were designed to test the hypothesis that insulin exerts some influence on the migrating myoelectric complex (MMC) pattern in the intestine and that its postprandial release results in a disruptive factor. Jejunal myoelectric activity was studied in conscious dogs and sheep after either the i.v. injection of exogenous insulin or the stimulation of insulin release. In dogs, the MMC was replaced by a continuous pattern of activity after the injection of insulin (1 U/kg, i.v.) or the infusion of D-glucose, L-leucine, or L-arginine. The response to feeding was reduced in alloxan diabetic dogs and was completely abolished following additional vagotomy when only exogenous insulin induced the "fed" pattern. Vagotomy alone had only minor effects on the response to feeding. Sheep exhibited a continuous sequence of MMC, regardless of feeding, but the infusion of insulin (3 IU/kg) or volatile fatty acids [60 nmol acetic acid (C2), n-butyric acid (C4), or a mixture of C2, propionic acid, or C4 in a molar ratio of 2:1:0.5; 10 ml/min at intervals of 3 days] produced activity similar to that observed after feeding in dogs. In alloxan diabetic sheep, the recurrence and intensity of the MMC were decreased, and the effect of volatile fatty acids was eliminated. The injection of insulin restored the pattern to normal. Thus, insulin levels are important in the control of the jejunal motor profile and may mediate the postprandial disappearance of MMC in dogs.

8467 GASTRIC MYOELECTRICAL ACTIVITY IN MAN. (Eng.) Roze, C. (Laboratoire de Gastroenterologie A Clinique des Maladies de l'Appareil Digestif Hopital Bichat, 75877 Paris Cedex 18, France). *Scand. J. Gastroenterol.* 10(Suppl. 35):54-79; 1975.

Studies on gastric electrical activity in man are summarized. For routine physiological studies in man, the only method available involves the use of a mucosal electrode. The limitations of the use of the electrode include: difficulty in holding the electrode in place for long periods, especially when the stomach is vigorously contracting; the limited area in which electrical activity is conveniently recorded (i.e., the terminal antrum); the inability of the electrode to record spike potentials; and the inability of this method to be used for the determination of the propagation velocity of control activity or the existence of coordination or disorganization of the electrical pattern, because only a single electrode probe has been successfully used. The relationship between gastric control activity and gastric emptying was studied during the emptying of three liquid test meals (350 ml of 150 mM saline, 75 mM HCl made iso-osmolar with NaCl, or 555 mM glucose). The results suggested that gastric control activity was modified during the emptying of the test meals and that the period of pacesetter potentials increased more with slowly emptying meals than with rapidly emptying ones. The infusion of saline (25 ml/min) into the duodenum had no effect, while acid (4 ml/min) induced a progressive increase in the pacesetter potential period, reaching a peak value of 43% above the basal level. A bolus injection of secretin (0.5 U/kg) to fasted subjects induced a consistent increase in the period of pacesetter potentials, which was 35% above the basal level. Although this suggests that hormonal effects are responsible for the effects of duodenal acidification, other studies have negated this. When HCl (0.75 mEq/min) was infused intraduodenally over 4 min in norma subjects, there was a clear increase in the period of gastric pacesetter potentials; when an identical infusion was carried out 20 min later, and followed by an i.v. bolus injection of secretin (0.5 U/kg), the effect was smaller. This increase seen in controls after acid infusion was not seen in patients with duodenal ulcer; however, there was a response to exogenous secretin. The results suggest that in duodenal ulcer patients there is a failure in gastric inhibitory mechanisms, which originates in the duodenum.

he therapeutic effectiveness and the effect on
astric secretion of intrajejunal drop feeding were
tudied in 143 patients with gastric ulcer and in
5 patients with duodenal ulcer. Group 1 (102 pa-
ients) received milk (1,000 ml), sour cream (100 g),
eggs, butter (25 g), sugar (160 g), protein hydro-
yzate (500-1,000 g), grape juice (500 ml), and,
n some cases, alcohol (50 g). Group 2 (76 patients)
eceived an emulsified mixture of dried milk (125 g),
ried skim milk (75 g), egg powder (50 g), sugar
90 g), and sunflower-seed oil (30 g). The gastric
ecretory response was lowest, and the production of
ancreatic juice and the activity of the proteolytic
nzymes were highest in group 2. The emulsion was
ell tolerated by the patients, and it promoted the
ormalization of some indices of protein and fatty
etabolism. The incidence of gastric and intestinal
yspepsia was higher in group 1 than in group 2.
ube feeding resulted in the cessation of pain in all
atients, which recurred in only four after the
ube feeding. Cicatrization of the ulcer was achieved
n 46.5% of the patients; this rate increased to
1.4% after adjuvant L-dopa treatment and to 65.5%
fter intestinal administration of a mixture of
rocaine hydrochloride, atropine, and metacin.

480 ISOLATION OF PARIETAL CELLS FROM GUINEA-
PIG GASTRIC MUCOSA AND THE IMMUNOLOGICAL
HARACTERIZATION OF THEIR ANTIGENIC STRUCTURE. (Eng.)
Jewell, D. P.; Katiyar, V. N.; Rees, C.; Taylor, K. B.; Wright, J. P. (Dept. Medicine, The Royal Free Hosp., Pond St., London, NW3 2QG, England). *Gut* 16(8):603-612; 1975.

Parietal cells were isolated from the Hartley guinea pig gastric mucosa by enzymatic digestion with collagenase. An *in vivo* perfusion with collagenase was not successful, and isolation was attempted by incubating fresh mucosa with collagenase (0.05%) *in vitro*. The cells were harvested by centrifugation and identified by phase-contrast microscopy, electron microscopy, immunofluorescence, and their ability to take up neutral red. Carbonic anhydrase and pepsin activities were also measured in the isolated cells and in the mucosal fragments from which they had been isolated. Rabbits were immunized with whole parietal cells, homogenized cells, the cell membranes from parietal cells, and soluble protein from the body of the guinea pig stomach. Antibody production was then determined by immunofluorescence, complement fixation, immunoelectrophoresis, and immunodiffusion. The *in vitro* technique yielded a suspension that contained 70%-80% parietal cells. About 80% of the cells were viable immediately after incubation, but viability dropped sharply after 1 hr. Antibodies to four distinct parietal cell antigens were obtained from rabbits immunized with the isolated parietal cells or fractions thereof. These antibodies were directed against the microsomal fraction of the parietal cell cytoplasm, the plasma and nuclear membranes, the soluble proteins, and Castle's intrinsic factor. The antibody against the microsomal fraction reacted in the same way as the antibody to parietal cell canaliculi found in the serum of patients with pernicious anemia, but it showed greater species-specificity. Preliminary studies of absorption with human, hog, and frog *(Rana catesbiana)* gastric microsomal preparations suggest that both pernicious anemia sera and rabbit antisera to guinea pig parietal cells contain a heterologous antibody to frog parietal cell cytoplasm.

8481 SOME MINIMAL EFFECTS OF BILE ACID ON CANINE GASTRIC MUCOSA IN HEIDENHAIN POUCHES.

(Eng.) Rees, W. D. W.; Rhodes, J.; Wheeler, M. H.; Meek, E. M.; Bartholomew, C.; Newcombe, R. G. (Univ. Hosp. Wales, Heath Park, Cardiff, Wales CF4 4XW). *Am. J. Dig. Dis.* 21(8):645-648; 1976.

Changes in the volume, concentration, and fluxes of sodium and hydrogen ions were measured in the gastric mucosa of Heidenhain pouches in four dogs before and during exposure to a concentration of taurocholate that was just sufficient to produce consistent changes. The results were examined to identify those changes that are the most sensitive indicators of bile damage. In periods 1 and 2 of the experiment (30 min each), a control standard acid solution containing 100 mM HCl was placed in the pouches, and changes in volume and ionic concentrations were determined. In period 3 (30 min), a solution of sodium taurocholate containing the same hydrogen ion concentration was used. The concentration of taurocholate used in each dog was determined by a series of preliminary experiments in which the concentration of taurocholate was increased until the results in period 3 differed consistently from the control periods. The concentrations used were 12, 20, 16, and 10 mM, resp. With sodium taurocholate in the pouch, the volume of fluid increased (mean 1.2 ml); associated with this were a marked and consistent fall in the hydrogen ion concentration (mean 4.7 µmol/ml) and an increase in the sodium ion concentration (3.7 µmol/ml). There was an increased flux of hydrogen ion from the pouch (mean 181 µmol/30 min) and of sodium into the pouch (mean 199 µmol/30 min). All changes were significantly different from the control periods. The change in volume in period 3 compared with period 2 was consistently positive and was approximately 1 ml in each dog. The ratio between bile/control value (for period 2) in ion flux was 1.6. The ratios for hydrogen ion concentration, sodium ion concentration, and sodium ion flux were all similar: 3.6, 3.4, and 4.1, resp. An analysis of individual results revealed that bile produced consistent changes in all parameters in all of 16 experiments. The change in hydrogen ion flux, however, was less consistent; in four experiments with different dogs, the change was not statistically significant. The results show that the hydrogen ion flux is the least sensitive indicator of minimal damage to the mucosal barrier.

8482 MODIFICATION OF THE GASTRIC SECRETORY RESPONSE TO SHAM FEEDING BY ACIDIFICATION OF THE ANTRUM AND THE DUODENUM IN DOGS.

(Eng.) Sjodin, L. (Dept. Pharmacology, Karolinska Institutet, Stockholm, Sweden). *Acta Physiol. Scand.* 96 (2):250-255; 1976.

The effect of closure of a gastric cannula on the
acid response to sham feeding was studied in Pavlo
pouch dogs with intact antro-duodenal regions, as
well as in antrectomized dogs with gastroduodenostomies. In the latter, the sham feeding response
was augmented by infusions of low doses of exogeno
gastrin (0.15 or 0.30 µg/kg/hr). Closure of the
gastric cannula resulted in a decreased acid respo
to 10 min of sham feeding in the four dogs tested
before antrectomy. The reduction in 3-hr acid output ranged between 39 and 71%. The reduction was
statistically significant ($p<0.05$) in at least one
1-hr period in all dogs. After antrectomy, the do
responded only weakly to sham feeding alone (dog A
0.68 ± 0.37; B, 0.92 ± 0.33; and C, 0.06 ± 0.06 mE
3 hr). When a threshold dose of gastrin was admin
tered as a background stimulus, the acid response
to sham feeding was substantial. This response wa
not reduced in any of three dogs by closure of the
gastric cannula and tended to increase the secreti
evoked by sham feeding. The secretin of pepsin
after sham feeding was not consistently affected b
closure of the gastric cannula. The changes in 3-hr output varied from an increase of 36% to a 66%
decrease. After antrectomy, there was again no
consistent difference in the pepsin response to sh
feeding between experiments with open ended and cl
gastric cannula. The results suggest that the
observed hypersecretory response to sham feeding
after diversion of gastric acid from antrum and
duodenum is mainly due to inactivation of antral
inhibitory mechanisms. The pepsin secretion follo
ing sham feeding was not consistently changed by
closure of the gastric cannula.

8483 INFLUENCE OF THE POSITION OF THE SIDE C HYDROXY GROUP ON THE GASTRIC ANTISECRET AND ANTIULCER ACTIONS OF E$_1$ PROSTAGLANDIN ANALOGS.

(Eng.) Dajani, E. Z.; Driskill, D. R.; Bianchi,
G.; Collins, P. W.; Pappo, R. (Searle Labs., P.O.
Box 5110, Chicago, IL 60680). *Prostaglandins* 10(
733-745; 1975.

Two synthetic prostaglandins (PG) were prepared a
compared with prostaglandin E$_1$ methyl ester (PGE$_1$
for their gastric antisecretory and antiulcer pro
ties in laboratory animals. The compounds were (
15-deoxy-16α, β-hydroxy PGE$_1$ methyl ester (SC-289
and (±)-15-deoxy-17α, β-hydroxy PGE$_1$ methyl ester
(SC-30693). Both SC-28904 and PGE$_1$ME, at a bolus
dose of 10 µg/kg, significantly inhibited steady-
gastric secretion in dogs with Heidenhain pouches.
PGE$_1$ME was significantly more potent only during
first interval, but SC-28904 was considerably lon
acting (120 min, compared to 90 min). Electrolyt
composition of the gastric fluid was not affected
this concentration. At 30 µg/kg, a significantly
greater inhibition of steady-state gastric secret
was effected. The two agents were equipotent, bu
28904 was longer acting (3 hr as compared to 2 hr
at the higher concentration. Both agents caused
increase in the sodium concentration of the gastr
juice and a decrease in hydrogen ion. At 1 mg/kg
SC-20693 was totally inactive. Intragastric bolu
administration of SC-28903 (300-1,000 µg/kg) to d
with gastric fistulae significantly reduced hista-

e-stimulated gastric secretion, but 100 µg/kg
ineffective. Intragastric administration of
$_1$ME (1 mg/kg) was totally ineffective in reducing
tric secretion in response to histamine and was
ociated with extensive biliary reflux, vomiting,
emesis. The incidence and severity of side
ects after i.v. PGE$_1$ME were much greater than
se observed after SC-28904. Intragastric adminis-
tion of SC-28904 at 300-1,000 µg/kg was only
asionally and briefly associated with side-effects.
antiulcer studies, forced muscular exercise
duced deep glandular mucosal ulceration and bleed-
; in all 78 control rats. S.c. administration of
her SC-28904 or PGE$_1$ME resulted in a dose-dependent
ibition of ulcer formation. In these studies,
-30693 was totally inactive, even at 5.0 mg/kg,
ch was 10 times greater than the minimal effective
se for SC-28904 or PGE$_1$ME. It is concluded that
e of the receptor sites for the PGE$_1$ molecule
ld easily accomodate the side chain hydroxy group
either the C$_{15}$ or C$_{16}$ position. The hydroxy
up in the latter position significantly improved
biological activity of PGE$_1$ME.

34 EXAMINATION OF STOMACH WALL Mg^{2+}-Na$^+$-K$^+$-
DEPENDENT ATPase, ATP, AND ADP IN PYLORUS-
GATED RATS. (Eng.) Mozsik, G.; Vizi, F. (First
pt. Medicine, Univ. Medical Sch., H-7643 Pecs,
ngary). *Am. J. Dig. Dis.* 21(8):649-654; 1976.

stomach wall contents of Mg^{++}-Na$^+$-K$^+$-dependent
Pase, ATP, and ADP were determined in rats at
7, 17, and 24 hr after ligation of the pylorus
release the H$^+$ secretion and ulcer development.
cer development was first observed at 17 hr and
s sharply increased by 24 hr. The peak of gastric
id secretion was reached by 7 hr after ligation,
ile the gastric secretory volume increased steadi-
throughout the 24 hr. Cation-dependent ATPase
tivity in the stomach wall from both the fore-
omach and the corpus plus antrum was markedly
creased at 4 and 7 hr and was significantly de-
eased at 24 hr. In both the forestomach and the
rpus plus antrum, the stomach wall ATP content
s markedly reduced at 4 hr, showed a rise at 7 hr,
d decreased thereafter. Changes in the stomach
ll ADP content paralleled those of ATP, but were
ch smaller. The peak of ouabain (0.25 mg, s.c.,
mediately after ligation) inhibition on gastric
tion-dependent ATPase activity was found at 4 hr
ter ligation in both the forestomach and the cor-
s plus antrum. Ouabain also inhibited gastric
id secretion and the development of ulcers. It is
ggested that H$^+$ secretion depends primarily on
eakdown of ATP, while ulcer development depends on
e exhaustion of ATP resynthesis.

SECRETION AND METABOLISM

Pancreas

8496 INHIBITORY ACTION OF ANTIDIURETIC HORMONE ON CANINE PANCREATIC EXOCRINE FLOW. (Eng.) Schapiro, H. (Eastern Virginia Medical Sch., Norfolk, VA 23507). *Am. J. Dig. Dis.* 20(9):853-857; 1975.

The effects of various antidiuretic hormone (ADH) preparations on pancreatic exocrine secretion and of minimal effective concentrations of ADH on pancreatic exocrine flow were studied in 14 fasted dogs with pancreatic fistulas. Pancreatic flow in anesthetized and conscious animals was stimulated by i.v. secretin (0.02 U/kg/min). ADH (Pitressin or Octapressin) was injected i.v. (1.0-5.0 mU/kg), and the pancreatic volume was measured at 5- to 10-min intervals. In some dogs, the minor pancreatic duct was ligated and the major duct was cannulated prior to secretin administration. After the ADH experiments, desamino-cys-1-8-D-arginine (5.0-600.0 ng/kg) was administered to the anesthetized dogs, and the effects on exocrine pancreatic flow were monitored. In both the anesthetized and conscious dogs, there was a correlation between the percentage inhibition of secretin-stimulated pancreatic exocrine flow and the amount of Pitressin administered; the minimal effective concentration was 1.0 mU ADH/kg or 0.016 mU ADH/ml blood. Sodium pentobarbital anesthesia greatly reduced the effects of secretin on pancreatic exocrine flow. The inhibitory effects of Octapressin on secretin-stimulated pancreatic exocrine secretion were greater and longer-lasting than those of Pitressin. The minimal effective dosage of Octapressin was 0.75 mU/kg or 0.012 mU/ml blood. Desamino-cys-1-8-D-arginine had no effect on the pancreatic exocrine flow in the anesthetized dogs. The data appear to demonstrate a correlation between the inhibitory action of ADH on the exocrine pancreas and the molecular configuration of the hormone.

8497 INHIBITION BY SOMATOSTATIN OF PANCREATIC JUICE AND ENZYME SECRETION AND GALLBLADDER CONTRACTION IN MAN INDUCED BY SECRETIN AND CHOLECYSTOKININ-PANCREOZYMIN. (Ger.) Creutzfeldt, W.; Lankisch, P. G.; Folsch, U. R. (Medizinische Universitatsklinik, 34 Gottingen, Humboldtallee 1, W. Germany). *Dtsch. Med. Wochenschr.* 100(20):1135-1138; 1975.

The effect of somatostatin on exogenously stimulat pancreatic secretion and gallbladder contraction w analyzed. Five healthy male volunteers received somatostatin (SS) at a rate of 200 μg/hr in a 2-hr infusion, after a bolus injection of 200 μg/hr. Secretin (0.33 U/kg) was administered i.v. 30 min after the beginning and end of the infusion. Chol cystokinin-pancreozymin (CCK-PZ) replaced secretin under the same conditions in the same subjects 7 days later. Assay of duodenal secretion showed a reduction of 44% of the basal volume, 30% of the bicarbonate output (but a 23% increase of the bica bonate concentration), 44% of amylase output, and 73% of trypsin secretion following SS suppression of secretin stimulation. SS inhibition of CCK-PZ stimulation was 61% of the basal volume, 58% of amylase output, 91% of trypsin output, and 93% of bilirubin. Pancreatic response to CCK-PZ 30 min after suspending SS showed a sharp increase in secretory volume and enzyme output. This was simu taneous with a significant increase in bilirubin concentration, indicating renewal of gallbladder contraction. There was also a complete arrest of gastric juice production, but blood sugar remained unaffected. There were no subjective side-effects SS is believed to inhibit the liberation of secret granules from endocrine cells, enzyme granules fro exocrine cells, acid from parietal cells, and the secretion of fluid from epithelial cells.

8498 FURTHER EVIDENCE THAT PROTEIN SYNTHESIS CAN BE DECREASED IN VIVO FOLLOWING HORMONAL STIMULATION IN THE RAT PANCREAS. (Eng.) Mongeau, R.; Dagorn, J. C.; Morisset, J. (Unite de Recherche Gastro-intestinale, Faculte des Sciences Universite de Sherbrooke, Sherbrooke, Quebec, Canada J1K 2R1). *Can. J. Physiol. Pharmacol.* 54(3 305-313; 1976.

The influence of exocrine secretory stimulation on pancreatic protein synthesis was investigated *in vivo* in male albino Sprague-Dawley rats. The stimulant consisted of a single injection of cholecys-

okinin pancreozymin (8 Ivy U/kg) plus secretin
5 clinical U/kg). The rate of ^{14}C-phenylala-
ine incorporation into total proteins was measured
, 11, 17, 30, 45, and 60 min later. Incorporation
as decreased by 34% ($p<0.001$) after 5 min, then
ncreased by 37% ($p<0.05$) at 17 min, and finally
eturned to control values at 45 min. This biphasic
volution was shown not to be caused by variations
n the precursor pool specific radioactivity. It
s concluded that secretory stimulation of the
ancreas can induce a decrease in the rate of pro-
ein biosynthesis. This decrease is a transient
henomenon, since the rate of biosynthesis was
ncreased at 17 min. These results, obtained from
totally *in vivo* system, confirm previous data
btained from an *in vivo-in vitro* system.

499 INTERACTION OF PORCINE VASOACTIVE INTES-
TINAL PEPTIDE WITH DISPERSED PANCREATIC
CINAR CELLS FROM THE GUINEA PIG: BINDING OF RADIO-
ODINATED PEPTIDE. (Eng.) Christophe, J. P.;
enlon, T. P.; Gardner, J. D. (Univ. Brussels
edical Sch., 1000 Brussels, Belgium). *J. Biol.
hem.* 251(15):4629-4634; 1976.

he kinetics, stoichiometry, and chemical specificity
f the binding of ^{125}I-labeled vasoactive intestinal
eptide (VIP) to dispersed acinar cells of guinea
ig pancreas are reported. Binding was half-maximal
ithin 5 min, and maximal at 10-20 min. It progres-
ively decreased with decrements in temperature from
7 C to 4 C. Binding was maximal at pH 7.0-7.5.
he addition of nonradioactive VIP (5×10^{-7} M) did
ot affect the rate of dissociation, but a reduction
n temperature did reduce the rate of dissociation.
he VIP was 94-97% precipitable by 5% trichloracetic
cid (TCA), and this was reduced by 15% after incuba-
ion for 30 min without acinar cells. In the pre-
ence of acinar cells, the rate of loss of TCA-pre-
ipitability increased two- to threefold, and non-
abeled VIP, bacitracin, or aprotinin did not pro-
ect against this loss. Increasing the concentration
f bovine serum albumin from 0.1% to 4% did increase
he TCA-precipitable VIP after 30 min from 69 to
3%. Following incubation of VIP with acinar cells,
he amount of free VIP in the incubation medium
hich could bind to fresh acinar cells diminished
rogressively with time at a rate more rapid than
he loss of TCA-precipitability. This deterioration
n biological activity was reduced when the tempera-
ure was lowered to 15 C. When bound VIP was
emoved from the acinar cells and reincubated with
resh acinar cells, it had significantly greater
iological activity than the free VIP from the same
ncubation mixture. Inhibition of binding of ^{125}I-
IP by native VIP was detected at 10^{-10} M VIP, half-
aximal at 10^{-9} M VIP, and complete at 10^{-6} M VIP.
he dose-response curves for inhibition of binding
y nonlabeled VIP and by secretin was biphasic and
uggested two classes of binding sites on the acinar
ells: a relatively small number of sites (9,000
er cell) with a high affinity for VIP and a low
ffinity for secretin; and a larger number of sites
135,000 per cell) with a low affinity for VIP and
high affinity for secretin. Since synthetic COOH-
erminal fragments VIP$_{14-28}$, VIP$_{15-28}$, and secretin$_{14-27}$ were equipotent in inhibiting binding, it is concluded that the difference between the relative affinities of VIP and secretin for the high affinity binding sites is primarily attributable to the NH$_2$ terminal portions of the molecules. Secretin$_{5-27}$, (6-tyrosine) secretin, and native secretin were equipotent in inhibiting VIP binding to its high affinity site, and were five times more potent than secretin$_{14-27}$, but 10,000 times less potent than native VIP.

SECRETION AND METABOLISM

Hepatobiliary Tract

LIBRARY U. OF I. [illegible]

8510 A NOVEL METHOD FOR RELIABLE LONG-TERM CANNULATION OF THE COMMON BILE DUCT IN DOGS. (Ger.) Dinstl, K.; Lehr, L.; Schiessel, R. (I. Chirurg. Univ. Klinik, Alser Str. 4, A-1090 Wien, Austria). *Res. Exp. Med.* 165(3):297-300; 1975.

A new method of bile drainage or measurement in which the instrumentation can remain in place for several months is reported. The method was tested in nine dogs. After median laparotomy, cholecystectomy, presentation of the ductus choledochus, and location of the hepaticus bifurcation, a siliconized T-drain was inserted and pulled through a Thomas cannula in the abdominal wall below the right rib cage. To avoid intestinal prolapse the interior cannula opening was covered with parietal peritoneum. There was no postoperative mortality. There was one infection of the cannula bed and two subcutaneous cannular prolapses, all of which were corrigible. The duration of cannulation was 2-9 months. Bile removal did not discomfit the animals and can be performed several times daily. The drain can be washed once monthly with sterile salt solution, and the cannular cavity can easily be sprayed with antibiotic.

8511 PROTECTION OF THE HEPATIC PARENCHYMA. (Ger.) Orzechowski, G. (5 Koln 91, Wiehlerstrasse 7, W. Germany). *Z. Ther.* 12(1):1-13; 1974.

Cell structure and function is reviewed, and the role of external and internal membranes in maintaining hepatocyte integrity is examined. Cell organelles were described, to illustrate how each can be construed as a series of interlocking interfaces making up the intracellular continuum. Particular stress was given to the inter-relation of membrane and enzyme and the mechanism of liver enzyme liberation to the serum. Various theories of membrane composition were examined to explain the transit o nonlipid protein structures across lipid barriers. The reversible effect of steroids on the permeabil ty of limiting cell membranes, such as the cortiso induced whitewash effect in icterus, was recalled. The type and extent of free radical attack on membranes was exemplified by carbon tetrachloride. The special reactivity of free radicals with methy ene bridges surrounding double bonds in unsaturate fatty acids was used to show free radical shift an the resultant chain reaction, leading ultimately t hydrophilic pore formation and the escape of intra cellular enzymes. Extensive coverage was devoted to silymarin and its antioxidant activity in parti ular as it protects against D-galactosamine injury, which, in the opinion of some, comes close to viral hepatitis infection in humans. Compartmentalization of lipid-soluble water-soluble compo nents received confirmation from the behavior of microsomal mixed function oxidases, which improve the water solubility of xenobiotics by introducing hydroxyl groups. In general, parenchymal protecti is synonymous with membrane protection.

8512 STUDIES ON CYTOCHROME P-450-LINKED FUNCTIONS IN ISOLATED RAT LIVER CELLS. (Eng Orrenius, S.; Moldeus, P.; Vadi, H.; Grundin, R. (Dept. Forensic Medicine, Karolinska Institutet, S-104 01 Stockholm 60, Sweden). *Biochem. Soc. Trans.* 3(6):817-820; 1975.

Studies on drug uptake, regulation of drug metabolism, and formation and excretion of drug metabolites in isolated rat liver cells are reviewed. T rat liver cells were isolated by collagenase perfusion. In the isolated liver microsomal fraction cytochrome P-450 is present in the oxidized state, and the major part appears to be free of bound endogenous substrate; this seems to be also true wit isolated rat liver cells. Thus, the addition of various drug substrates to the medium causes the

pearance of the type I spectral change indicative
the formation of the cytochrome P-450-substrate
mplex. At a temperature compatible with metabo-
sm, the type I spectral change produced on the
dition of drugs, such as alprenolol or nortripty-
ne, to a suspension of rat liver cells is often
llowed by the appearance of an absorption peak at
7 nm that then rapidly disappears. This spectral
ange is in turn followed by another transient in-
ease in absorption at about 446 nm. The occur-
nce and short duration of these absorption peaks
ring the early phase of drug mono-oxygenation sug-
st that they may reflect different states of cyto-
rome P-450 during the mono-oxygenation reaction.
e mono-oxygenation of various substrates with iso-
ted rat liver cells is as fast as, or faster than,
at with the isolated liver microsomal fraction
pplemented with an NADPH-generating system. With
l tested substrates, both experimental models have
sponded similarly to inhibitors, such as diethyl-
inoethyl 2,2-diphenylvalerate and 2-methyl-1,2-
pyrid-3-ylpropan-1-one, and to pretreatment of the
imals with inducers, such as phenobarbital or 3-
thylcholanthrene. In studies with isolated liver
crosomal fractions, NADH affects microsomal mono-
ygenase reactions, stimulating drug metabolism in
nergism with NADPH. This may be due to increased
patic reduction level leading to increased produc-
on of NADPH, transfer of electrons from reduced
tochrome b_5 to the reduced oxygenated substrate-
und cytochrome P-450 complex, or simply a de-
eased flow of electrons from NADPH-cytochrome P-450
ductase to cytochrome b_5. Whether a glucuronide or
sulfate is formed when drug metabolites are hy-
oxylated seems to be dependent on substrate con-
ntration, as well as on the availability of uri-
ne diphosphate-glucuronic acid and ATP-5'-sulphato-
osphate. The results of these experiments suggest
at isolated liver cells seem to retain many prop-
ties of the intact tissue, which makes them suit-
le for cytochrome P-450-linked functions that can-
t be easily investigated with other experimental
stems.

13 INHIBITORY AND ANTI-INHIBITORY FACTORS OF RAT SERUM ACTIVE ON THE G_1-S TRANSITION OF PATOCYTE CELL CYCLE.

(Eng.) Nadal, C.; Boffa, G.
(Unite de Physiologie Cellulaire INSERM, Institut
Radium, 91405-Orsay, France). *Cell Tissue Kinet.*
4):297-205; 1975.

e factors regulating hepatic cell multiplication
vivo were localized by fractionation of the serum
oteins of normal and two-thirds hepatectomized
star rats. Rat pups (8-10 days old) were inocula-
d s.c. with 0.4 ml of casein solution (3.5 g in 3%
ueous NaOH). Twelve hours later, during the late
phase in the casein-synchronized hepatocytes, the
imals received s.c. injections of 0.15 M NaCl
.5 or 0.8 ml), normal or hepatectomized adult rat
rum (0.8 ml), various rat serum protein fractions
.5 ml), or a second dose of casein (0.4 ml).
ring the S phase, 4 hr later, the synchronized
patocytes were labeled by an i.p. injection of
-6-thymidine (1 µCi/g). The percentage of labeled
patocyte nuclei and of binucleated hepatocytes
among labeled daughter cells was determined 40 hr after the first casein injection. The injection of normal adult rat serum in late G_1 produced a constant reduction in the percentage of labeled hepatocyte nuclei, reflecting inhibition of the progression from G_1 to S, and an increase in the percentage of binucleate hepatocytes. The activity of the various serum fractions indicated that the effect of the crude serum was linked to proteins having a high electronegative charge and high molecular weight. Polyacrylamide gel electrophoresis showed that the main component of the active fraction was α_1-macroglobulin. Hepatectomized rat serum had no inhibiting activity and did not induce binucleate cell formation. However, two components with antagonistic activities (an α_1-globulin and a γ-globulin) were separated chromatographically from this serum. The α_1-globulin had a lower molecular weight than that of normal rats, and only male rat pups were responsive to it. The γ-globulin factor was antagonistic to the α_1-globulin factor, although a similar fraction from normal rat serum had no such antagonistic activity. The existence in adult rat serum of a factor inhibiting hepatocyte multiplication and of an occasional antagonist suggests a control mechanism similar to that observed in systems regulated by tissue-specific inhibitors of the chalones.

8514 DRUG METABOLIZING FUNCTION OF ISOLATED PERFUSED LIVER.

(Eng.) Noda, T.; Araki, K.; Koida, M.; Kaneto, H. (Dept. Pharmacology, Nagasaki Univ., Nagasaki, Japan). *Jpn. J. Pharmacol.* 25(3):325-333; 1975.

The isolated liver perfusion technique was used to study the disappearance patterns of foreign compounds *in vivo* and the influence of drug pretreatments to stimulate or depress liver function in male Wistar rats. The animals received phenobarbital sodium (80 mg/kg/day, i.p.) for 4 days, ethionine (100 mg/kg/day, i.p.) for 2 days, or saline for 2 or 4 days, after which their livers were perfused (120 ml). In the phenobarbital-pretreated liver, the disappearance rates of *p*-nitrophenol (PNP, 32 µmol in the perfusate initially) and hexobarbital (HEX, 100 µmol) were significantly accelerated. Ethionine pretreatment reduced the disappearance rates of HEX, BSP, and inodocyanine green (ICG). When phenobarbital or ethionine was added directly to the perfusate of livers from untreated rats, there was no change in the disappearance pattern of BSP. When the control liver was perfused with the medium containing BSP, over 20% of the dye was recovered from the bile within 1 hr. Phenobarbital pretreatment markedly accelerated the excretion rate, while ethionine decreased the excretion rate to about one-half of the control level. ICG excretion (2% after 1 hr) was unaffected by phenobarbital and was decreased with ethionine. PNP excretion (3% after 40 min) was accelerated by phenobarbital pretreatment. Phenobarbital pretreatment increased the flow rate of perfused liver when BSP or PNP was added to the perfusate. This effect was masked in the presence of HEX or ICG in the medium. Ethionine pretreatment reduced the flow rate, and the effect was not influenced by the compound added to the perfusate. Since the results obtained with the perfused liver parallel those of *in vivo* liver function, the isolated perfused liver is useful for the direct study of the liver as a drug metabolizing tissue.

8515 ON THE MECHANISMS OF BILIARY EXCRETION OF THE BILIARY CONTRAST MEDIUM IOGLYCAMIDE IN THE GUINEA PIG RELATIVE TO BILE FLOW. (Ger.) Klapdor, R.; Valerius, H.; Zschukke, N. (I. Medizinische Klinik der Universitat Hamburg, Hamburg, W. Germany). *Res. Exp. Med. (Berl.)* 167(3):217-229; 1976.

The mechanistic role of bile flow in the distribution and biliary excretion of the contrast medium ioglycamic acid and the response of the medium to bile acid or secretin stimulation of bile flow was examined in cholecystectomized guinea pigs. The physiology of bile excretion in the guinea pig was found to replicate that for other experimental animals. Bile excretion of ioglycamic acid was limited by a biliary transport maximum. It was also excreted against a concentration gradient in bile (the concentration ratio of ioglycamic blood to ioglycamic bile was 1:34). Both results suggest active ioglycamic excretion in the bile. The bile flow, biliary ioglycamic acid concentration, and excretion were closely correlated to maximize the transport maximum. There was also a significant positive linear correlation between its transport maximum and basal bile flow; there was no positive correlation between transport maximum and maximum concentration in bile, both of which variables remained relatively constant. The choleretic activity of ioglycamic acid would explain the positive correlation between transport maximum and maximally stimulated bile flow. It follows that there is a positive correlation between basal and maximal flows. Neither stimulation of canalicular bile flow by bile acids nor ductal flow by secretin induced an increased ioglycamic acid excretion per unit of time; with augmented bile flow, the concentration in bile decreased proportionately, so that the transport maximum could remain constant. The independence of transport maximum and bile flow means that biliary ioglycamic acid concentration is dependent on bile flow.

LIBRARY U. OF I. [illegible]

8516 MECHANISMS OF BILE SECRETION IN GUINEA PIGS. (Ger.) Klapdor, R.; Schliewe, J.; Valerius, H. (Univ.-Krankenhause Eppendorf, D-2000 Hamburg 20, Martinistrasse 52, W. Germany). *Res. Exp. Med. (Berl.)* 166(3):241-251; 1975.

Species differences in bile formation by guinea pigs were examined in a series of experiments. Spontaneous bile flow and total bile acid pool, with and without phenobarbital (PHB), effect of i.v. choleretics, and erythritol clearance were measured in 21 animals. After interruption of enterohepatic circulation, there was an initial decline in bile flow and bile acid pool, both of which were linearly correlated. The slope of the regression line suggested there was both a bile acid-dependent and bile acid-independent fraction of bile volume. In fasting, 92% of the bile acid pool was stored in the gallbladder; 8% was in the enterohepatic circulation. PHB treatment led to an increase in the bile salt-independent fraction, which is stimulated by choleretics in other species. Taurocholate, i.v., induced both an elevation in bile flow and the bile acid pool, and, consequently, to an increase only in the bile salt-dependent fraction. Taurocholate and ioglycamide elicited an increase in erythritol clearance, as well as bile flow; secretin only increased bile flow. It follows that taurocholate and ioglycamide stimulate so-called canalicular bile flow, while secretin stimulates ductal bile flow. Low cholesterol and bilirubin and elevated LDH and HBDH were characteristic of guinea pigs.

8517 ENZYME HISTOCHEMICAL STUDIES OF RABBIT BILE DUCTS WITH AND WITHOUT BILE FLOW. (Eng.) Simert, G.; Hammar, E.; Hansson, J. A.; Hagerstrand, I.; Vang, J. (Lund's Hosp., Lund, Sweden). *Acta Pathol. Microbiol. Scand.* [*A*] 84(1): 33-39; 1976.

To determine whether bile influences enzyme patter in the extrahepatic bile ducts, the activities of 10 enzymes were studied histochemically in the duct of normal rabbits and in rabbits in which the comm duct had been tied and a cholecystoduodenostomy ha been performed. In the normal ducts, the alkaline phosphatase activity was mainly concentrated in the connective tissue, in the vessel walls, and in the cells situated immediately beneath the epithelium; this activity decreased gradually away from the lumen, and in the luminal epithelium, there was no activity. Acid phosphatase was weakly active in th epithelium, and there was an increase in activity close to the duodenum. ATP activity was found in the epithelium near the lumen. There was very strong subepithelial activity in the basal membrane and in the stromal vessel walls. Leucine aminopeptidase showed no activity in the epithelium, but there was strong activity in a narrow subepithelial zone corresponding to the basal membrane and modera activity in the stromal vessel walls and in the collagenous connective tissue. Nonspecific esteras showed an even cytoplasmic activity in the epitheli cells, but not elsewhere in the wall. The activity of β-glucuronidase was moderately pronounced in the epithelial cell cytoplasm, and there was no other activity in the wall. Succinic dehydrogenase was strongly active in the epithelium and only moderately active in the vessel walls. Monoaminooxidase was weakly active in the epithelium. LDH had an even cytoplasmic distribution, and its activ ity increased toward the duodenal mucosa. Gammaglutamyl transpeptidase activity was seen only in the cytoplasm of some of the deep crypts. After 24 hr of bile flow diversion, a distinct infiltration of polymorphonuclear leukocytes appeared, especially in the outer areas of the common duct; however, this appeared to be a response to the operative trauma, as it disappeared after 10 days. There were no changes in the enzyme activities or in the histological appearance of the bile duct below the ligature up to the end of the experiment, 30 days after operation.

BILE ACID METABOLISM IN MAMMALS: IX. CONVERSION OF CHENODEOXYCHOLIC ACID TO CHOLIC BY ISOLATED PERFUSED RAT LIVER. (Eng.) Yousef,
.; Fisher, M. M. (Dept. Pathology and Medicine,
. Toronto, Toronto, Ontario, Canada). *Lipids*
):571-573; 1975.

spectroscopy and radio gas chromatography were
to identify a trihydroxy bile acid synthesized
exogenous chenodeoxycholic acid (CDCA) by the
ated perfused rat liver. In 12 experiments on
Wistar rats of each sex, a mixture of 1 µmol
and 5 µCi radiolabeled (C^{14} in the C-24 posi-
) CDCA was purified by thin-layer chromatog-
y (TLC) before addition to the perfusion medium.
other six experiments were carried out in male
; 10, 20, or 30 µmol of CDCA was added to the
usion medium. Each perfusion was continued for
following the addition of CDCA. Bile acid
yl esters of the various perfusions were pooled,
erted to trimethylsilyl esters and analyzed by
mbined gas-liquid chromatography—mass spectro-
y system and by radio gas chromatography. In
rol experiments in which no exogenous bile acid
added to the perfusion medium, biliary secretion
ile acids in 3 hr was negligible. When 1 µmol
was added to the perfusion medium, 91 and 89%
he bile acid was secreted in the bile produced
he livers of male and female rats, resp. Beta-
cholic acid accounted for 10% of the biliary
acids in females and 38% in males. CDCA
unted for 60% of biliary bile acids in females
31% in males. In both male and female rats,
ydroxy bile acid, previously identified as
ic acid, accounted for approximately 30% of the
ary bile acids secreted. There was no signifi-
difference in specific activity of β-muricholic,
, or trihydroxy acid as measured by direct count,
-liquid chromatography quantitation of various
bands of methyl esters, or by radio gas chroma-
aphy. In studies using the livers of male rats
10-30 µmol CDCA, it was found that the amount
-muricholic acid secreted in the bile increased
ressively as the amount of CDCA added to the
usion increased. This was not the case for
ic acid. These studies demonstrate that mammal-
liver can hydroxylate (12α) the ring structure
ile acids after oxidation of their side chain.
low perfusion medium concentrations of CDCA,
t 30% CDCA can be converted to cholic acid. The
acity of isolated perfused liver of the male rat
convert CDCA to cholic acid appears limited.

CONVERSION OF CHOLESTEROL INTO BILE ACIDS AND REGULATION OF THIS PROCESS. (Rus.)
isova, O. K. (Inst. Experimental Medicine, USSR
l. Medical Sciences, Leningrad, USSR). *Vopr. Med.*
n. 21(5):461-469; 1975.

lies on the biosynthesis of bile acids from cho-
terol and on the regulation of this process are
iewed. Bile acids are synthesized by the liver
n the catabolic cholesterol pool originating from
degradation of lipoproteins. The oxidation of
lesterol to cholic acid includes such reactions
7-α- and 12-α-hydroxylations, stereospecific reduction of the C_5-C_6 double bond, inversion of the 3-β-hydroxyl group into a 3-α-hydroxyl group, and the degradation of the cholesterol side chain, leading to a carboxyl group at C_{24}. The common precursor of cholic and chenodeoxycholic acids is believed to be 7-α-oxycholest-4-en-3-one, which is converted to 7-α-oxy-5-β-cholestan-3-one, and further to 5-β-cholestan-3-α, 7-α-diol. The latter is hydroxylated in the C_{26} position to 5-β-cholestan-3-α, 7-α-26-triol, which is ultimately converted into chenodeoxycholic acid. The coenzyme A esters of bile acids are synthesized in the liver and conjugated with taurine and glycine. This process is catalyzed by lysosomal acyl transferase and regulated by diet, vitamins, and hormones. The conjugated cholic and chenodeoxycholic acids undergo enzymatic deconjugation and 7-α-dehydroxylation in the small intestine to form deoxycholic and lithocholic acid, resp. The biosynthesis of bile acids is controlled by the quantity of the bile acids returning to the liver within the enterohepatic circulation by a negative feedback. The biosynthesis of bile acids is considerably influenced by thyroid, gonadal, pituitary, and adrenal hormones.

8520 SYNTHETIC CAPACITY AND CELL METABOLITES OF BILE DUCT OBSTRUCTED RAT LIVERS. EFFECT OF FREE AND CONJUGATED DIHYDROXY BILE ACIDS. (Eng.)

Liersch, M. A.; Hesse, W. (Medizinische Klinik der Universitat, 69 Heidelberg, Bergheimer Str. 58, W. Germany). *Acta Hepatogastroenterol.* 22(5):281-289; 1975.

Liver cell metabolites were measured, and the capacity of the perfused cholestatic rat liver to produce glucose, urea, and ketone bodies was examined. In addition, the influence of dihydroxy bile acids on normal and bile duct-ligated rat livers was studied. The concentrations of adenine nucleotides, lactate, pyruvate, 3-hydroxybutyrate, acetoacetate, glucose, and uridine diphosphate-glucose in the cholestatic livers were not significantly different from those in sham-operated control livers. The glycogen content of the cholestatic livers was 50% lower than that in normal livers. Gluconeogenesis from lactate and urea production from ammonium chloride were only slightly reduced in bile-duct obstructed livers. Protein content in the bile duct-ligated livers (62.6 mg/g) was decreased in comparison with that in normal livers (86.3 mg/g). The administration of 0.25 mM taurochenodeoxycholate or chenodeoxycholate did not affect the metabolism of normal or cholestatic livers. Ketone body production from oleate (150 µmol) was reduced to 66% in bile duct-obstructed livers, and the addition of 0.25 mM taurochenodeoxycholate to the perfusion medium of the cholestatic livers further reduced this value to 45% of normal. In contrast to previous studies, chenodeoxycholate induced neither cholestasis nor a marked fall in the ATP content of normal livers of female Wistar rats.

8521 INFLUENCE OF (+)-CYANIDANOL-3 ON BILE FLOW AND BILIRUBIN EXCRETION IN HETEROZYGOUS GUNN RATS. (Eng.)

Horak, W.; Seyfried, H.; Grabner, G. *In: New Trends in the Therapy of Liver Diseases. Proceedings of the International Symposium on New*

Trends in the Therapy of Liver Diseases, Tirrenia, 6-7 June 1974. Bertelli, A., ed. (New York: S. Karger): pp. 110-113; 1975.

The effect of (+)-cyanidanol-3 on bile flow and biliary bilirubin excretion in heterozygous Gunn rats weighing 200-320 g was investigated. Animals of one group were treated for 6 weeks with daily s.c. injections of (+)-cyanidanol-3, 5 mg/100 g body weight; those of the second group received phenobarbital, 8 mg/100 g body weight, and those of the control group received 0.5 ml saline. Bilirubin transport maximum was assessed by an infusion of unconjugated bilirubin (0.2 mg/min/100 g). Treatment with phenobarbital caused a significant increase in liver weight ($p<0.005$), bile flow ($p<0.05$), and maximum biliary bilirubin excretion ($p<0.005$). The respective values were 3.40 g/100 g body weight, 8.00 μl/min/100 g, and 50.20 μg/min/100 g; control values were 2.40 g/100 g, 7.00 μl/min/100 g, and 28.50 μg/min/100 g. The bilirubin transport maximum was augmented not only by increased bile flow and by an increase in total and conjugated bilirubin concentrations in the bile. Treatment with (+)-cyanidanol-3 had no effect on liver weight, bile flow, and bilirubin excretion. These results do not explain the accelerated decrease of serum bilirubin levels in patients with acute viral hepatitis treated with (+)-cyanidanol-3. The effect of this drug is apparently different from the action of phenobarbital.

8522 SIGNIFICANT PATHWAYS OF HEPATIC ETHANOL METABOLISM.

(Eng.) Thurman, R. G.; McKenna, W. R.; Brentzel, H. J., Jr.; Hesse, S. (Johnson Res. Foundation, Univ. Pennsylvania, Philadelphia, PA 19174). *Biol. Alcohol Alcoholism* 34(11):2075-2081; 1975.

The mechanism of microsomal ethanol oxidation is reviewed. Rat liver microsomes oxidize ethanol two to three times faster than propanol when incubated with either an NADPH- or an H_2O_2-generating system. In addition, solubilized purified microsomal subfractions contain protein with an electrophoretic mobility identical to rat liver catalase on sodium dodecyl sulfate-polyacrylamide gels, suggesting that the separation of catalase from cytochrome P-450 and other microsomal components may not be feasible. These data support the hypothesis that catalase is responsible for NADPH-dependent microsomal ethanol oxidation. Direct readout techniques for pyridine nucleotides, the catalase-H_2O_2 complex, and cytochrome P-450 were used to evaluate the specificity of inhibitors of alcohol dehydrogenase (4-methylpyrazole, 4 mM) and catalase (aminotriazole, 1.0 g/kg) qualitatively in perfused rat livers. 4-Methylpyrazole and aminotriazole are specific inhibitors for alcohol dehydrogenase and catalase, resp., under these conditions. When used alone or in combination, neither inhibitor altered the mixed function oxidation of p-nitroanisole to p-nitrophenol, as observed by oxygen uptake and product formation. When ethanol utilization was measured over a concentration range of 20-80 mM in perfused liver, a concentration dependence was observed. At low concentrations of etha-
nol, ethanol oxidation was almost abolished by 4-
methylpyrazole; however, the contribution of 4-me
pyrazole-insensitive ethanol uptake increased as
a function of ethanol concentration, and at 80 mM
ethanol, ethanol utilization was nearly 50% methy
pyrazole-insensitive. This portion of ethanol ox
dation was abolished by aminotriazole. The data
indicate that alcohol dehydrogenase and catalase-
H_2O_2 are responsible for hepatic ethanol oxidatio
At low ethanol concentrations (<20 mM), alcohol d
drogenase is predominant, but at concentrations u
to 80 mM, the contribution of catalase-H_2O_2 to ov
all ethanol utilization is significant. There wa
no evidence for involvement of the endoplasmic re
ulum in ethanol metabolism in the perfused liver.

8523 THE EFFECT OF ACUTE ALCOHOLIC POISONING THE SYNTHESIS OF RNA AND PROTEINS IN TH LIVER OF RATS AT DIFFERENT TIMES OF THE DAY.

(Ru
Latenkov, V. P. (Tyumen Medical Inst., Tyumen, US
Farmakol. Toksikol. 39(1):101-104; 1976.

The effect of acute ethanol intoxication on prote
and RNA synthesis by hepatocytes was studied in m
albino rats at different times of the day by auto-
radiographic study of ^{3}H-uridine and ^{35}S-methioni
incorporation in hepatocyte nuclei and cytoplasm.
Two groups of rats weighing 150 g received a sing
dose of 80-proof ethanol (1.5 ml/kg) through gast
tube at 9 a.m. or 9 p.m.; they were sacrificed 12
hr later, 2 hr after the i.p. administration of
labeled uridine and methionine. The uridine labe
indices in the control group were 2.88% at 9 a.m.
and 5.4% at 9 p.m. in the hepatocyte nuclei, and
at 9 a.m. and 54.4% at 9 p.m. in the cytoplasm.
the test group, the nuclear labeling indices were
1.78% at 9 a.m. and 2.11% at 9 p.m.; the cytoplas
labeling indices were 14.8% at 9 a.m. and 27.6% a
9 p.m. The nuclear methionine labeling indices i
the control group were 3.46% at 9 a.m. and 5.46%
at 9 p.m. versus 24.1% at 9 a.m. and 49.1% at 9
p.m. in the cytoplasm. In the test group, the
methionine labeling indices were 3.53% at 9 a.m.
and 5.06% at 9 p.m. in the nuclei, and 21.2% at 9
a.m. and 32.9% at 9 p.m. in the cytoplasm. The
findings indicate the considerable inhibitory act
of ethanol on protein and RNA synthesis by hepato
cytes, and persistence of the endogenous diurnal
rhythm of protein and RNA synthesis, even under
the influence of ethanol.

8524 EFFECTS OF A CHOLINE-DEFICIENT DIET ON INDUCTION OF DRUG- AND ETHANOL-METABOL ENZYMES AND ON THE ALTERATION OF RATES OF ETHANO DEGRADATION BY ETHANOL AND PHENOBARBITAL.

(Eng.
Mezey, E.; Potter, J. J.; Brandes, D. (Baltimore
City Hosp., Baltimore, MD 21224). *Biochem. Phar
macol.* 24(21):1975-1981; 1975.

A choline-deficient diet was fed to male Wistar
to determine the effect *in vivo* of alterations i
phospholipids on microsomal enzyme systems, on
ethanol-oxidizing enzymes, on rates of ethanol m
olism, and on the adaptive responses of all para-

ers to ethanol and phenobarbital administration.
one series of experiments, the animals received
holine-deficient or a choline-supplemented diet,
h either ethanol or sucrose making up 36% of the
ories. In a second series of experiments, the
s were fed the choline-deficient (2.0 g dihydrogen
rate/100 g diet) or choline-supplemented diets
3 weeks; for 5 days during the last week of
ding, half of the animals in the choline-deficient
choline-supplemented groups received i.p. injec-
ns of sodium phenobarbital (80 mg/kg), and the
er half, i.p. injections of saline. In both exper-
nts, choline deficiency resulted in increased
al liver lipids. In the first series, the values
e 54.5 and 259.2 mg/g in choline-supplemented
choline-deficient animals on sucrose diets, resp.,
52.1 and 187.5 mg/g in animals on ethanol diet,
p. In the second series, the levels were 69.8
253.2 mg/g in animals on choline-supplemented
choline-deficient diets alone, and 64.6 and 237.6
g, resp., in animals treated with phenobarbital.
total liver triglycerides, the values in the first
ies were 11.5, 100.4, 13.9, and 66.9 mg/g, resp.;
the second series, they were 6.1, 106.6, 8.9, and
.2 mg/g, resp. Total phospholipids decreased in
animals on the choline-deficient diets, due pri-
ily to a decrease in phosphatidylcholine. Choline
iciency did not result in changes in microsomal
ymes or parameters of ethanol metabolism. It did
vent optimal induction of aniline hydroxylase
ivity by both ethanol (14.0 nmol/mg/hr versus
7 nmol/mg/hr in ethanol-treated animals on supple-
ted diet) and by phenobarbital (15.0 nmol/mg/hr
sus 23.3 nmol/mg/hr in phenobarbital-treated
mals on supplemented diet) and optimal induction
cytochrome P-450 activity by ethanol (1.43 nmol/
versus 1.76 nmol/mg) and by phenobarbital (1.69
l/mg versus 1.90 nmol/mg). Optimal induction of
rosomal protein concentration and cytochrome b_5
phenobarbital, and ethanol-induced increases, both
the activity of microsomal ethanol-oxidizing
tem and in the rates of ethanol disappearance
m the blood, were also reduced. Alcohol de-
rogenase activity remained unchanged. The results
onstrate that dietary choline is required for
imal induction of microsomal enzymes by both
anol and phenobarbital and for increases in
anol metabolism induced by ethanol administration.
is suggested that a decrease in available hepatic
sphatidylcholine, due to choline deficiency, is a
se of inhibition of the optimal induction of
rosomal enzyme.

5 IMMUNOCHEMICAL RELATIONSHIP BETWEEN α-AMYLASES OF RAT LIVER, SERUM, PANCREAS

PAROTID GLAND. (Eng.) Messer, M.; Dean, R. T.
pt. Biochemistry, Univ. Sydney, Sydney, N.S.W.
6, Australia). *Biochem. J.* 151(1):17-22; 1975.

immunochemical relation between α-amylases in
rat liver, serum, pancreas, and parotid gland
studied using rabbit antisera to purified rat
otid gland amylase and to crude rat parotid
nd extract. Antisera was prepared by injecting
h purified (anti-B and anti-C) and crude (anti-
rat parotid gland extract i.m. into New Zealand
White rabbits. Agarose gel double-diffusion of purified parotid gland, serum, and liver amylase preparations gave a single continuous precipitin line against anti-A, -B, and -C. A precipitin line was also seen with pancreatic amylase, but only at high concentrations (500 U/ml). When parotid gland, serum, or liver amylases were allowed to electrophorese into agarose gel containing antisera B or C, single rocket-shaped precipitin lines were seen in each. The ratios of antisera B to amylase in the precipitin lines were: 0.38, 0.34, 0.32, and 10 µl/U for parotid gland, serum, liver, and pancreatic amylase, resp. The ratios were: 1.7, 1.7, and 1.6 µl/U with antisera C for parotid gland, serum, and liver amylase, resp. The inhibition curves for serum and liver amylase were identical, and were similar to the curve for parotid gland amylase, but were very different from that of pancreatic amylase; 50% inhibition was produced by 0.46, 0.46, 0.56, and 39 µl antiserum/amylase unit, resp. After immunoprecipitation, there was further loss of activity with pancreatic amylase. It is concluded that rat liver and serum amylases are identical and are closely related to parotid gland amylase. All three are significantly different from pancreatic amylase and are produced by different genes. These data support the suggestion that the liver is the main source of serum amylase.

8526 POSSIBLE MECHANISM OF INDUCTION OF LIVER MICROSOMAL MONOOXYGENASES BY PHENOBARBITAL.

(Eng.) Tsyrlov, I.-B.; Zakharova, N. E.; Gromova, O. A.; Lyakhovich, V. V. (Academy Medical Sciences USSR, Siberian Branch, Novosibirsk 630091, USSR). *Biochim. Biophys. Acta* 421(1):44-56; 1976.

The mechanisms involved in the induction of microsomal monoxygenases by 3-methylcholanthrene or phenobarbital were studied, using a model in which maximal induction by 3-methylcholanthrene was followed by phenobarbital treatment in male Wistar rats. 3-Methylcholanthrene treatment (50 mg/kg/day, i.p.) for 2 days led to an increase of up to 185% in the CO-binding hemoprotein content in the form of cytochrome P-448; the subsequent discontinuation of treatment with the inducer had practically no effect on the amount of P-448 during the next 2 days. The administration of phenobarbital (100 mg/kg/day, i.p.) alone for 2 days caused an increase of up to 235% in the amount of cytochrome P-450. After maximal induction by 3-methylcholanthrene, phenobarbital treatment led to an increase in the hemoprotein content of up to 350% of the control value, i.e., there was an evident additive effect resulting from the consecutive induction by two drugs. At the same time, there was a considerable gain in the content of low-spin species in hemoprotein, without an accompanying rise in the content of its high-spin species. Treatment with both inducers increased the velocity of the rapid phase of the NADPH-dependent reduction of CO-binding hemoprotein to a level corresponding to 205% of the rate seen in the control preparations. In addition, there were considerable increases in the rates of microsomal aminopyrine and aniline metabolism. The activity of aminopyrine *N*-demethylase was also elevated.

The data indicate that the location of the CO-peak of $Na_2S_2O_4$-reduced hemoprotein is not the criterion of monoxygenase functional specificity; the latter is possibly defined by the relation between the contents of the high-spin and low-spin species of the cytochrome.

8527 THE TOPOGRAPHICAL LOCATION AND UNIQUE NATURE OF A GLUCOKINASE ASSOCIATED WITH THE GOLGI APPARATUS OF RAT LIVER.

(Eng.) Berthillier, G.; Coleman, R.; Walker, D. G. (Dept. Biochemistry, Univ. Birmingham, P.O. Box 363, Birmingham, B15 2TT, England). *Biochem. J.* 154(1):193-201; 1976.

To confirm the existence of a glucokinase in the Golgi apparatus, and to examine its topographical relationships, a Golgi-rich fraction was prepared directly from the livers of Wistar rats. The activities of UDP-galactose-*N*-acetyl-glucosamine galactosyltransferase and thiamin pyrophosphatase were enriched 15- and 13-fold, resp., in the Golgi preparation, in comparison to the whole homogenate. Glucose 6-phosphatase and glucose 6-phosphate dehydrogenase activities were not detectable in the Golgi fraction, excluding contamination by both endoplasmic reticulum and cytosol. Precise evaluation of particulate glucokinase activity in the homogenate was not possible because of the relatively large quantity of soluble enzyme; glucokinase activity was enriched in the Golgi preparation fivefold over that in the material applied to the density gradient. Phosphofructokinase, aldolase, and pyruvate kinase activities were not detected in the Golgi preparation, and only a trace of lactate dehydrogenase was present. The latter could easily be removed by washing with 3 M KCl. A procedure that disrupts the entire membrane structure was always required for the measurement of glucokinase activity in Golgi preparations. The typical latency curve obtained for the effect of Triton X-100 showed that, above a final concentration of 0.015%, membranes began to be disrupted, allowing the penetration of substrates to the site of the enzyme. Four successive freezing and thawing operations were necessary to liberate all latent activity from Golgi vesicles. The nonliberation of phospholipids of the membranes by this procedure suggested that no membrane fragments are present in the supernatant, where all the glucokinase activity is finally recovered. Hence glucokinase is unlikely to be embedded in the lipid layer of the Golgi membranes. Glucokinase solubilized from the Golgi preparation did not cross-react with an antiserum prepared against cytoplasmic glucokinase and showed different affinity from the cytoplasmic enzyme for concanavalin A. In diabetic and neonatal rat livers, the activities of Golgi glucokinase were similar to those found in the adult animal, suggesting that the two glucokinase enzymes do not have the same metabolic role in the liver cell. A portion of the total hepatic activities of UTP-glucose 1-phosphate uridyltransferase and phosphoglucomutase also appeared to be located in the Golgi apparatus. Together with the glucokinase, these two enzymes would facilitate the biosynthesis of UDP-glucose from glucose.

8528 RECYCLING OF GLUCOSE BY RAT HEPATOCYTES.

(Eng.) Katz, J.; Wals, P. A.; Golden, S.; Rognstad, R. (Cedars-Sinai Medical Res. Inst., 4751 Fountain Ave., Los Angeles, CA 90029). *Eur. J. Bi* *chem.* 60(1):91-101; 1975.

To establish and quantitate the recycling of gluco in hepatocytes from fed and fasted rats, the metab lism of glucose labeled uniformly with ^{14}C, and in positions 2, 3, and 5, with ^{3}H was studied. Cells w incubated with glucose as the sole substrate or wi glucose and a variety of glucose precursors, and t uptake or production of glucose and the utilizatio of the isotopes were determined. There was no glu cose uptake at concentrations of up to 15 mM. ^{14}C was, however, recovered in CO_2, lactate, and amino acids, and ^{3}H was recovered in water. Considerabl incorporation from ^{14}C- and ^{3}H-labeled glucose int glycogen occurred at high glucose concentrations (>20 mM). The yield in water always exceeded that in ^{14}C-labeled products. The yield in ^{3}HOH from [2-^{3}H]glucose exceeded that from [5-^{3}H]glucose, an the latter was greater than from [3-^{3}H]glucose. Utilization of labeled glucose did not follow Michaelis-Menton kinetics. The fractional rate of uptake of ^{14}C- and ^{3}H-labeled glucose increase with glucose concentration, with a maximum at abou 15 mM, and then declined. The effect of gluconeogenic substrates on the isotope utilization and th ^{3}H/^{14}C ratio in glycogen was studied. The ^{14}C uptake was always depressed. Addition of lactate and dihydroxyacetone had little effect on the detr tiation of [2-^{3}H]glucose, but it was depressed by other substrates. The detritiation of [3-^{3}H]- and [5-^{3}H]glucose was depressed in gluconeogenesis, an that from [3-^{3}H]glucose was usually depressed mor than from [5-^{3}H]glucose. In the presence of lact detritiation of [3-^{3}H]glucose was about half that from [5-^{3}H]glucose. The estimate of glucose phos phorylation required the determination of the spe fic activity of glucose 6-phosphate from [2-^{3}H]gl cose. It appeared that futile cycling between gl cose and glucose 6-phosphate was extensive in cel with a high glycogen content, but was low in cell from starved rats, and was nearly absent in those from diabetic animals. The estimation of the pho phorylation of fructose 6-phosphate in the presen of cycling requires knowledge of the specific act ties of fructose 6-phosphate and fructose 1,6-bis phosphate from [3-^{3}H]glucose. At present, there are no adequate data to calculate phosphorylation and recycling of fructose 6-phosphate, but under some conditions, the rate may be quite high.

8529 CELLULAR METABOLITE DISTRIBUTION AND TH CONTROL OF GLUCONEOGENESIS IN THE PERFU ISOLATED RAT LIVER.

(Eng.) Parrilla, R.; Ayuso-Parrilla, M. S. (Dept. Metabolism, Instituto G. Maranon, C.S.I.C., Velazquez 144, Madrid-6, Spain *Pfluegers Arch.* 362(1):49-54; 1976.

To study the hepatic intracellular distribution o certain metabolites under conditions of perfusion of the isolated organ, glucose production wa measured in isolated Wistar rat livers perfused with 100 ml of blood-free recirculating medium. gluconeogenic rate, using L-alanine as substrate, was only 55% of that obtained with L-lactate. Th steady-state concentration of gluconeogenic and tricarboxylic acid cycle intermediates were measu

reeze clamped biopsies. In comparison with
r perfused with L-alanine, livers perfused with
ctate displayed higher concentrations of malate
n 1,186 versus 616 nmol/g), α-glycerophosphate
34 versus 643 nmol/g), and β-hydroxybutyrate
29 versus 1,572 nmol/g), probably as a result of
gher state of reduction of the nicotinamide
em. Hexose-phosphate intermediates were also
htly increased when L-lactate was the substrate.
omparison with livers perfused with L-alanine,
livers perfused with L-lactate had lower concen-
ions of phosphoenolypyruvate (466 versus 2,789
/g) and 3-phosphoglycerate (351 versus 6,127
/g). Livers perfused with L-lactate displayed
er cytosolic concentrations of all the tricarb-
ic acid cycle intermediates except oxaloacetate,
e glutamate was slightly higher, and aspartate
iderably higher, when alanine was the substrate.
he mitochondrial compartment, the pattern of
ribution tended to be the opposite; that is,
rs perfused with L-lactate showed lower concen-
ions of all the intermediates except α-ketoglu-
te. The mitochondrial:cytosolic metabolite
ients of all the intermediates whose distribu-
was studied were higher in livers perfused with
anine. During gluconeogenesis from alanine, an
ustation of the cytosolic α-ketoglutarate is
ably prevented by a continuous deamination of
amate; this implies that there must be a gluta-
mitochondrial entry and α-ketoglutarate exit.
, the rate of movement of any of these anions
ss the mitochondrial membrane or the activity
lutamate dehydrogenase may control pyruvate

sis.

THE EFFECT OF SOME GLUCOCORTICOIDS ON HEPATIC MICROSOMAL HYDROXYLATION IN THE
ND HAMSTER. (Eng.) Tredger, J. M.; McPherson,
.; Chakraborty, J.; Bridges, J. W.; Parke, D. V.
. Biochemistry, Univ. Surrey, Surrey GU 5XH,
Britain). *Naunyn Schmiedebergs Arch. Pharma-*
292(3):267-270; 1976.

effect of glucocorticoids on hepatic microsomal
enyl and aniline hydroxylations was investigated
le Wistar rats and golden syrian hamsters.
$^{-4}$ M, corticosterone, cortisol, 6-β-hydroxy-
costerone, prednisolone, betamethasone, dexa-
asone, or 3,4-benzpyrene produced little change
e biphenyl-4-hydroxylase and aniline-4-hydroxy-
activities *in vitro*. In contrast, 10^{-4} M pred-
one, corticosterone, dexamethasone, and beta-
asone produced 65%, 104%, 163%, and 680% increas-
microsomal biphenyl-2-hydroxylase activity,
None of these steroids caused a similar
ease in biphenyl-2-hydroxylation when hamster
microsomes were used. When betamethasone was
istered *in vivo* (36 μmol/kg, i.p.), cytochrome
and biphenyl-4-hydroxylase activities were
ally depressed in both rats and hamsters,
as aniline hydroxylase activity was marginally
r than the control values. A slow rise in all
parameters then followed in both species.
48 hr, the increased enzyme activities and
hrome P-450 contents continued up to the term-

ination of the experiment at 64 hr in the hamster, but not in the rat. In the hamster, after the administration of betamethasone, a gradual rise in the biphenyl-2-hydroxylase activity was observed, which became prominent after 24 hr and rose to 260% and 380% of control values at 48 hr and 64 hr, resp. In the rat, a sharp rise in biphenyl-2-hydroxylation occurred after betamethasone administration, peaking at 4 hr to 440% of the control level. An equally rapid fall in the enzyme activity then followed, reaching almost the control values again in 8 hr. Biphenyl-2-hydroxylase activity then rose again to 410% and 458% of the control levels at 48 hr and 64 hr, resp. In view of the specificity, the rate and magnitude of the enhancement of biphenyl-2-hydroxylase activity, especially with betamethasone, and the fact that the effect can be produced very rapidly in microsomal preparations devoid of DNA, *de novo* protein synthesis cannot be involved. The most likely explanation is that it is the result of interaction of the steroid with the endoplasmic reticulum, causing a specific configurational change, which is expressed as an increase in biphenyl-2-hydroxylase activity.

8531 COMPARATIVE STUDIES IN BLOOD, BILE AND URINE TO THE BILIARY EXCRETION AND MULTI-COMPARTMENTAL ANALYSIS OF GLYCOCHOLIC ACID IN THE UNANESTHETIZED PIG.
(Ger.) Klapdor, R.; Bolte, J.; Schlosser, G. A. (Univ.-Krankenhaus Eppendorf, I. Medizinische Klinik, D-2000 Hamburg 20, Martinistr. 52, W. Germany). *Res. Exp. Med. (Berl.)* 166(3):209-219; 1975.

An experimental model for comparing blood, bile, and urine variables in mechanistic studies of bile excretion and multicompartmental assay of conjugated bile acids was developed in young pigs. After T-drain insertion, cholecystectomy, and establishment of fasting values, the distribution and excretion kinetics of labeled glycocholic acid (GA) were quantified in nonanesthetized animals. On interruption of the enterohepatic circulation, the bile volume and total bile acid excretion decreased, but the bilirubin remained constant. A linear correlation was found between bile volume and acid, suggesting a bile salt-dependent fraction, but the slope of the regression line also indicated the presence of a bile salt-independent fraction. Three-compartment analysis of GA excretion found 80% excreted with the bile after 50 min and 83% after 90 min; less than 1% was detected in urine after 90 min. This method is useful for the study of the distribution and excretion kinetics of conjugated bile acids, especially ^{14}C-glycocholic acid, by a 3-compartmental analysis.

8532 SPLANCHNIC VASCULAR RESPONSES TO THE INFUSION OF PROSTAGLANDINS A_1, A_2, AND B_1.
(Eng.) Hanson, K. M.; Post, J. A. (Dept. Physiology, Ohio State Univ., 333 West Tenth Ave., Columbus, OH 43210). *Pharmacology* 14(2):166-181; 1976.

The effects of prostaglandins A_1, A_2, and B_1 (PGA_1, PGA_2, and PGB_1) on the vasculature of the liver and small intestine were studied in 73 dogs. Infusion of PGA$_1$ into branches of the superior mesenteric artery in isolated autoperfused segments of the small intestine at rates of 1, 2, and 50 μg/kg/hr resulted in a significant decrease in resistance and a significant increase in blood flow. The responses peaked after 1 min of infusion, at which time the mean decreases in resistance were 21.2, 30.8, and 51.4%, resp., for the three dose rates, and the mean increases in blood flow were 22.3, 31.9, and 87.3%, resp. When the largest dose was infused into the femoral vein, the dilator response peaked after 2 min, with a mean 17.3% decrease in resistance. β-Adrenergic blockade with sotalol (20 mg/kg) did not affect the response. The response of the small intestinal vasculature to the intra-arterial (i.a.) infusion of PGA$_2$ (50 μg/kg/hr, 10 min) was essentially the same as that seen with PGA$_1$, although the initial vasodilation was less intense (decrease in resistance=31.9%, increase in blood flow=46.0%). During the infusion of PGA$_2$ in the femoral vein, the resistance was decreased 19.2% after 2 min. When PGA$_1$ and PGA$_2$ infusion (i.v. or i.a.) was continued beyond 1 or 2 min, the vasodilation response was lost and converted to vasoconstriction; this response was more pronounced with PGA$_2$. When PGA$_1$ was infused into the hepatic artery, the resistance was decreased, and this was most intense and best sustained at a rate of 50 g/kg/hr; after 1 min, resistance was decreased 23.8%, and after 10 min it was still decreased 21.0%, while the accompanying increase in flow was only one-half that existing at 1 min. The decline in blood flow was paralleled by a decline in arterial pressure. This was most evident during femoral venous infusion of PGA$_1$, when arterial pressure began to decrease almost immediately after the onset of infusion and was decreased 28.6% after 10 min. Hepatic artery flow also fell throughout the entire period of i.v. infusion. Systemic arterial pressure was reduced during i.v. infusion to about three times that seen when infusion was directly into the liver by hepatic arterial or portal venous perfusion. The effects of PGA$_2$ on the hepatic arterial bed and on systemic arterial pressure were similar to those of PGA$_1$, although hepatic artery dilation was less intense and less well sustained. PGB$_1$ had less cardiovascular action than did PGA$_1$ or PGA$_2$. The intrahepatic portal venous vessels were not constricted by PGA$_1$ or PGB$_1$. When evaluating the vascular effects of prostaglandins, the area under study, the route of administration, and the dose must all be considered.

8533 ADENOSINE 3',5'-MONOPHOSPHATE AND THE REGULATION OF RAT HEPATIC STEROL SYNTHESIS: A REEXAMINATION BASED ON SUTHERLAND CRITERIA. (Eng.)

Bricker, L. A.; Kozlovskis, P. L.; Levey, G. S. (Univ. Miami Sch. Medicine, P. O. Box 520875, Biscayne Annex, Miami, FL 33152). *Metabolism* 25(4): 477-481; 1976.

The previously reported ability of adenosine 3',5'-monophosphate (cyclic AMP) at supraphysiologic concentrations to suppress *in vitro* lipogenesis in the rat liver was further investigated to determine whether this suppression is actually a physiologic action of the nucleotide. Theophylline (1 mM), either alone or in combination with cyclic AMP (0.8 mM or 5 mM), did not augment the suppression of sterol synthesis. The effects of a number of compounds structurally related to cyclic AMP, including ATP, ADP, AMP, adenosine, coenzyme A, HMG-coenzyme A, cyclic GMP, uridine, guanosine, deoxythymidine, and ribose-5-phosphate (all at 5 mM) wer tested. All of these, with the exception of ribose 5'-phosphate, produced significant suppression of sterol synthesis (reducing the incorporation of (1-^{14}C)-octanoate into sterol from a mean control level of 1,440 disintegrations/min to 110-975 dpm), suggesting that the cyclic AMP-mediated suppression is not specific. These results suggest that the cyclic AMP-mediated suppression of sterologenesis is not a physiologic effect of the nucleotide.

8534 HEPATITIS IN PRIMATES. (Eng.) Deinhard

F. (Dept. Microbiology, Univ. Illinois Medical Center, Chicago, IL). *Adv. Virus Res.* 20: 113-157; 1976.

Hepatitis in primates is reviewed. Nonhuman primat associated hepatitis in man and transmission of hep titis A and B to nonhuman primates are discussed, and a historical review of attempts to isolate hepatitis viruses and hepatitis B antigen is prese ed. Nonhuman primates have played an important ro in the recent major and rapid advances in hepatiti research. They provide model systems for both hep titis A and B and, perhaps, for hepatitis C. The final definitive identification of the two or thre types of human hepatitis viruses can now be clearl foreseen, and vaccination against human hepatitis will probably be possible. Three events in the 1960's led to explosive progress in hepatitis research: the observation that nonhuman primates, and particularly chimpanzees, could transmit hepatitis to man and that "spontaneous" biochemically and histologically typical viral hepatitis occurre in recently caught chimpanzees; the observation that typical biochemical and histological hepatiti could be induced by parenteral or p.o. inoculation of acute phase sera or feces from human hepatitis A cases in certain species of marmoset monkeys and that disease could be passed serially from animal to animal; and the discovery of the Australia anti gen and its association with hepatitis B. Studies of the Australia antigen led to a recognition of the various morphological forms of hepatitis B surface antigen and the demonstration of the large Dane particle. These discoveries led to many impo tant practical advances, such as prescreening of blood and blood products for HBsAg to detect infec ivity; they also provided an accurate identificati of long-incubation or serum hepatitis as hepatitis B and its clear identification from hepatitis A and possibly C. It was also established that hepatitis B could be transmitted by means ot than direct s.c. or i.v. inoculation.

8535 IN VIVO MICROSCOPIC OBSERVATIONS OF THE PATHOGENESIS OF ACUTE MOUSE VIRAL HEPATI

(Eng.) Bloch, E. H.; Warren, K. S.; Rosenthal, M

t. Anatomy, Case Western Reserve Univ., Cleveland,
4106). *Br. J. Exp. Pathol.* 56(3):256-264: 1975.

livers of female CF-1 mice infected with MHV-3
l hepatitis (10^4 median tissue culture, i.p.)
examined microscopically *in vivo* to determine
extent of involvement of the hepatic microvas-
: system. Clinicopathologic examinations were
ormed to determine liver and spleen weights,
al pressures, hematocrits, liver function, and
degree of virus infection. The ratios of liver
spleen to body weight increased by day 2 of
ction and peaked on day 6. SGOT levels increased
ly 20-fold by day 4 and returned to normal by
; serum bilirubin doubled by day 3. Virus was
ted in the liver by the end of day 1, the
st titer was reached at the end of day 3, and
irus was no longer detectable by day 8. Post-
sections of the liver showed hepatic patholo-
aracterized by focal and coalescent necrosis.
vo microscopy showed localized areas where the
chyma, sinusoids, and blood were obliterated.
er, immediately peripheral to these lesions,
flow and vessels were unaffected, except for
ized hypertrophy of the Kupffer cells. Although
lesion produced a sinusoidal block to blood
portal hypertension did not occur even in the
nce of extensive focal and confluent necrosis.
mount of liver damage varied considerably from
l to animal. In general, the extent of pathol-
bserved *in vivo* correlated with the histologic-
ndings *in vitro*. The results suggest that
vascular thromboembolism is not involved in
hepatitis. However, the hepatic arteriolar
n probably plays a role in conjunction with
degree of vasodilatation of the sinusoid to
nsate for the sinusoidal block produced by the
-induced lesions.

PREVENTION BY STEROIDS OF CERIUM HEPATOTOXICITY.

(Eng.) Salas, M.; Tuchweber,
nstitut de medecine et de chirurgie experimen-
, Universite de Montreal, C.P. 6128 Montreal,
Canada). *Arch. Toxicol.* 35(2):115-125; 1976.

ffect of phenobarbital and several steroids on
lity, triglyceride content, and liver ultra-
ture was investigated in female Sprague-Dawley
after administration of $CeCl_3$. The animals
treated twice daily, p.o., with 100 mg/kg
enolone-16 α-carbonitrile (PCN), 19 mg/kg
ethasone, 100 mg/kg spironolactone, 60 mg/kg
barbital, and 100 mg/kg estradiol for 3 days
to treatment with 10 mg/kg $CeCl_3$, i.v. From
ys after $CeCl_3$ administration, there was a
ortality, which was totally abolished by pre-
ment with PCN ($p<0.05$) and estradiol ($p<0.05$)
rtially decreased by phenobarbital and spiro-
tone. All dexamethasone-treated rats died
ys postinjection of $CeCl_3$. Hepatic trigly-
concentrations decreased in all groups com-
with the $CeCl_3$-treated group, but the differ-
were statistically significant only in animals
ated with PCN ($p>0.01$), estradiol ($p>0.01$),
amethasone ($p>0.05$). Liver weights were sig-
ntly increased by phenobarbital ($p>0.001$),
>0.01), estradiol ($p>0.01$), and phenobarbital
($p>0.001$). Light and electron microscopy indicated that the hepatocytic damage elicited by $CeCl_3$ was decreased significantly by PCN, estradiol, and dexamethasone. The steroids may have altered the distribution and binding of the metal to the endoplasmic reticulum, thus protecting these membranes against the effect of cerium.

8537 EXPERIMENTAL STUDY OF THE HEPATOBILIARY TOXICITY OF LITHOCHOLIC ACID IN RABBITS.

(Fre.) Vachon, A.; Barthe, J.; Barthe, M. F.; Pichot, J.; Paliard, P.; Grimaud, J.; Hadj Aissa, A. (Clinique Medicale C, Hotel-Dieu, 1, place de l'Hopital, 69288 Lyon Cedex 1, France). *Ann. Gastroenterol. Hepatol.* 12(3):163-175; 1976.

Eleven rabbits received 50 mg lithocholic acid (LA) in standard daily dietary regimens for intervals up to 4 months before sacrifice. After 2 months, the dominant hepatic lesion was portal and periportal ductal proliferation associated with extensive sclerosis and periductal inflammation; perilobular cholestasis was frank. After 3 months, there was also evidence of portal and periportal fibrosis. At 4 months, the ductal proliferation was pronounced, and 50% of the parenchyma was occupied by infiltrative sclerosis. Animals receiving 50 mg LA for 3 months followed by standard diets showed little hepatic alteration, except for plasmocytic periportal inflammation. Serum levels confirmed a cholesterolemia and elevated γ-globulin. No ultrastructural changes were found up to 10 days after 50 mg LA. By day 20, the endoplasmic reticulum was enlarged; there was a further increase by day 30, without alteration of the vesicular architecture. At the hepatocyte poles there was a clear zone devoid of organelles. In some hepatocytes, dense and lamellar microbodies were found. Dilation of interhepatocyte bile canaliculi, with loss of microvilli, was pronounced. The LA activity was situated in the endoplasmic reticulum, confirming the hepatocyte origin of cholestasis.

8538 COMPARATIVE STUDIES OF LIVER FUNCTION BY MEANS OF ^{131}I-ROSE BENGAL FOLLOWING USAGE OF DIFFERENT CONVENTIONALLY EMPLOYED ANESTHETICS.

(Bul.) Atanasov, A.; Zakharieva, Z. (Faculty Medicine, Medical Sch., Plovdiv, Bulgaria). *Khirurgiia (Sofiia)* 28(3):236-242; 1975.

A comparative study of the effect of some commonly used anesthetics on rabbit liver function was conducted with ^{131}I-rose bengal (10 ml/kg diluted to 0.5 ml). The rabbits (110) were divided into four experimental groups: group 1 (50 animals) received narcotane (0.5-1.5 vol%) and the other three groups (15 animals each) received ether (2-5 vol%), petran (0.5-2 vol%), or neuroleptanalgesics. In group 1, anesthesia lasted for 2 hr (15 rabbits) or 4 hr (25 rabbits). In the other groups, anesthesia lasted for 4 hr. The depth of anesthesia was held at stage 3. The neuroleptanalgesics consisted of an initial dose of fentalin (0.10 mg) and dehydrobenzperidol (5 mg), followed by 0.05 mg of fentalin and 2.5 mg of dehydrobenzperidol at 0.5-hr intervals up to 4 hr (total dose: 0.50

mg fentalin and 25 mg dehydrobenzperidol). The following indices were recorded for a 2-hr narcotane anesthesia: time of maximum liver absorption (15.60 min), time of semiexcretion from liver (47.60 min), and time of semiexcretion of blood isotopes (14.13 min). These values are higher than normal (11.33, 36.30, and 7.73 min, resp.) and were even higher for a 4-hr narcotane anesthesia. Hepatography, taken 2 hr after narcotane anesthesia, showed that liver function was unchanged in 73.33% of the animals in group 1, with disturbed excretion in 20%, and disturbed absorption and excretion in 6.67% of the experimental cases. But after 4-hr ether anesthesia, liver function changes were essentially milder, while anesthesia with petran and neuroleptanalgesics presented no evidence of liver function impairment.

8539 COPPER-INDUCED SYNTHESIS OF COPPER-CHELATIN IN RAT LIVER. (Eng.) Premakumar, R.; Winge, D. R.; Wiley, R. D.; Rajagopalan, K. V. (Dept. Biochemistry, Duke Univ. Medical Center, Durham, NC 27710). *Arch. Biochem. Biophys.* 170(1): 267-277; 1975.

The role of RNA and protein synthesis in the formation and accumulation of Cu chelatin in the rat liver was studied in male Sprague-Dawley rats injected i.p. with $CuCl_2$ (2.5 mg Cu/kg). The livers were excised and homogenized, and the soluble protein fractions were analyzed by Sephadex G-75 elution. Cu was quantitated by atomic absorption spectroscopy. $CuCl_2$ injection led to the accumulation of Cu chelatin in the liver; this low molecular weight, Cu-containing protein was not detected in significant quantities in the livers of control rats, even after the *in vitro* addition of Cu to the liver homogenates. In control liver preparations, the Sephadex G-75 eluate fraction corresponding to Cu chelatin failed to bind Cu under conditions in which the apochelatin was reconstituted with the metal. A marked increase in the incorporation of (4,5-^{3}H)-lysine into Cu chelatin was observed when the amino acid was used for pulse-labeling 5.5 hr after Cu injection. The administration of cycloheximide or actinomycin D (1.5 mg/kg) to the rats prior to Cu exposure inhibited the incorporation of radioactive lysine into Cu chelatin markedly; these drugs did not prevent the hepatic accumulation of the metal. Under these conditions, the extraneous Cu was associated with the major protein components, with no detectable increase in the Cu chelatin fraction. The incorporation of 5-^{3}H-orotic acid into liver RNA was elevated in the Cu-treated rats, and the Cu-stimulated labeling of the RNA was abolished by actinomycin D pretreatment. The results provide evidence for the induction by Cu of the synthesis of Cu chelatin by a mechanism involving transcriptional control.

8540 SH GROUPS IN LIVER MITOCHONDRIA FROM RATS WITH ALTERED COPPER CONTENT. (Eng.) Ivancheva, E. A.; Russanov, E. M. (Inst. Physiology, Bulgarian Acad. Sciences, Sofia, Bulgaria). *C. R. Acad. Bulg. Sci.* 28(7):975-977; 1975.

The number of sulfhydryl groups (-SH) in liver mit chondria was quantitated by experimentally alterin the copper content of the mitochondria of male Wis rats. Mitochondria with higher or reduced Cu contents were obtained from rats kept on a Cu-deficie or a Cu-loaded (40 mg/kg/day) diet for 8 weeks. Mitochondrial Cu content was also increased by inj ting Cu (100, 500, and 1,000, i.p.) in rats 10 min before sacrifice. The SH groups were determined after pretreatment of the mitochondria with 0.3 mg lubrol/mg protein. Control mitochondria contained mean levels of 0.21 nM Cu/mg protein and 71 nM -SH protein. The corresponding values in the experime tal animals were: 0.15 nM Cu/mg protein and 52.27 nM -SH/mg in Cu-deficient rats; 0.56 nM Cu/mg and 37.30 nM -SH/mg in Cu-deficient rats; 0.28 nM Cu/m and 36.68 nM -SH/mg in animals given 100 μg Cu, i. 0.45 nM Cu/mg and 46.63 nM -SH/mg in rats given 50 μg; and 0.54 nM Cu/mg and 25.86 nM -SH/mg in anima given 1,000 μg. The results indicate that Cu catalyzes the oxidation of only part of the SH groups, the "copper accessible" ones. The authors assume that the transport of Cu in the mitochondri *in vivo* is based on the same mechanisms of transfe that take place *in vitro*.

SECRETION AND METABOLISM

Intestine

85 THE PANETH CELLS: REGULATION OF SECRETION DURING REFEEDING IN THE MOUSE AND HAMSTER.
re.) Balas, D. (Laboratorie d'Histologi-Embryolo-
e, U.E.R. des Sciences Medicales-Purpan, F 31077
ulouse Cedex, France). *Arch. Anat. Microsc. Mor-
ol. Exp.* 63(4):307-322; 1974.

e secretory response of Paneth cells in mice and
msters after refeeding following starvation was
vestigated. In both species, refeeding elicited
gnificant premature degranulation within 15 min,
process that began before the feeding ended.
ximum secretion occurred within 40-50 min. Degran-
ation was 25%-45% in the mouse and 70% in the hams-
r. Regranulation occurred in two stages: a rapid
assembly of two-thirds of the granules within 20-
min and a subsequent gradual replenishment of
e remaining one-third. Even at maximum, no Paneth
ll group was completely depleted, and some cells
ssessed zymogen granules. The secretion was held
the glandular lumina by parallel filaments, after
mediate liquefaction. For both species the secre-
ry response was more significant in the caudal
rt of the jejunum, since the cells in the cranial
junum were degranulated more gradually. This
idence excludes a local effect of foodstuffs on
e mucosa. In animals with a pyloric ligature
ere was no degranulation. In animals with a duo-
nal ligation 1.5 cm below the common duct, degran-
ation was 35% in the mouse and 40% in the hamster.
granulation also occurred upon refeeding of vago-
mized or atropinized hamsters. The Paneth cell response is evidently a hormonal reflex triggered by the entry of foodstuffs into the duodenum.

8586 CHARACTERIZATION, DISTRIBUTION AND BIOSYNTHESIS OF THE MAJOR GANGLIOSIDE OF RAT INTESTINAL MUCOSA. (Eng.) Glickman, R. M.; Bouhours, J. F. (Dept. Medicine, Beth Israel Hosp., Boston, MA 02115). *Biochim. Biophys. Acta* 424(1): 17-25; 1976.

Studies on the characterization, distribution, and biosynthesis of the major ganglioside of the rat intestinal mucosa are reported. Thin layer chromatography of the aqueous phase after chloroform/methanol extraction of the whole mucosa revealed that the major ganglioside had a mobility similar to that of the hematoside GM_3 in both mucosa and purified brush border. This was further separated chromatographically into its upper and lower portions. After hydrolysis with neuraminidase, a lipid product which appeared to be lactosylceramide was yielded by both the upper and lower portions. The sialic acid liberated from the lower component was *N*-glycolylneuraminic acid, while the minor upper component contained *N*-acetylneuraminic acid as the scialic acid moiety. The major ganglioside contained no amino acid on gas liquid chromatography, but it contained glucose, galactose, and sialic acid in equimolar ratios, confirming its identity as the hematosis GM_3. The hematoside content of crypt cells was significantly less than that of villus cells. Determination of CMP-sialic acid:lactosylceramide sialyltransferase activity in differentiated villus and undifferentiated crypt cells indicated much less activity in the crypt cells. It is concluded that marked differences in ganglioside content and biosynthesis occur in contiguous populations of cells in varying states of differentiation in the normal rat intestine.

8587 GLYCEROLIPID BIOSYNTHESIS IN ISOLATED RAT INTESTINAL EPITHELIAL CELLS. (Eng.)

O'Doherty, P. J. A.; Kuksis, A. (Dept. Biochemistry, Univ. Wisconsin, Madison, WI 53706). *Can J. Biochem.* 53(9):1010-1019; 1975.

Glycerolipid biosynthesis was studied in isolated epithelial cells prepared from the intestinal mucosa of fasted male Wistar rats by collagenase dispersion. Cellular glycolytic activity was measured by estimating the production of lactic acid from glucose, and the biosynthesis of triacylglycerols and phospholipids was determined by incubating radioactive glycerol and glucose with micellar solutions of fatty acids and the isolated intestinal epithelial cells. The structural and metabolic integrity of the isolated cells was verified by electron microscopy, a high percentage of Trypan Blue exclusion, a low degree of lactate dehydrogenase release into the medium, and by the retention of sensitivity to agents known to modify metabolic and transport activity in everted sacs of intestinal mucosa. The isolated cells actively incorporated labeled glucose, glycerol, 2-monoacylglycerol, and free fatty acids into glycerolipids without specific cofactor requirements. The addition of free fatty acids stimulated the incorporation of both glucose and glycerol into triacylglycerols and glycerophospholipids, the greatest effect being observed with palmitate. The stimulation of monoacylglycerol acylation appeared to depend on the nature of both the monoacylglycerol and fatty acid supplied. Stereospecific analyses of the diacylglycerols formed from 2-monoacylglycerols and free fatty acids showed that 1,2-diacyl-*sn*-glycerols (62%-70%) were the major and 2,3-diacyl-*sn*-glycerols (30%-38%) were the minor intermediates in triacylglycerol biosynthesis. The data indicate that isolated intestinal epithelial cells exhibit a total capacity of glycerolipid synthesis and a stereochemical course of reaction comparable to those observed for triacylglycerol formation in everted intestinal mucosa sacs, but much less specific than those seen in microsomal preparations of intestinal mucosa.

8588 INTESTINAL GLYCOPROTEINS OF GERMFREE RATS. IV. OLIGOSACCHARIDES OBTAINED BY CHEMICAL DEGRADATION OF A WATER-SOLUBLE GLYCOPROTEIN FRACTION.

(Eng.) Wold, J. K.; Smestad, B.; Midtvedt, T. (Inst. Pharmacy, Univ. Oslo, Oslo 3, Norway). *Acta Chem. Scand.* [B]. 29(6):703-709; 1975.

The carbohydrate side chains of a recently characterized water-soluble glycoprotein fraction from the intestinal mucus of germfree rats were studied, using both an alkali-borohydride degradation procedur and acetolysis. The mucus was subjected to alkali treatment in the presence of excess borohydride, followed by separation of acidic and neutral oligosaccharides on an AG 1 formate ion exchange column. Further fractionation by gel chromatography, prepar ative paper chromatography, removal of the sialic acid residues, and subsequent treatment with alkali borohydride furnished an oligosaccharide mixture; after deionization of the mixture, the degraded material was fractionated on a Bio-Gel P-2 column, and final separation was achieved by preparative paper chromatography. Two oligosaccharides (I and II), in addition to *N*-acetylgalactosaminitol, were isolated. Periodate oxidation of the *N*-acetylgalactosaminitol, followed by sodium borohydride treat ment, gave 2-*N*-acetylamino-1,3-propanediol. Weak a hydrolysis of oligosaccharide I gave fucose and a c pound with the chromatographic mobility of oligosac charide II; subsequent incubation of this compound with β-galactosidase resulted in the liberation of lactose and *N*-acetylgalactosaminitol. Methyl iodid methylsulfinyl carbanion methylation of oligosaccharide I in dimethyl sulfoxide resulted in the pro duction of methylated sugars; these sugars were represented by three peaks on gas liquid chromatograms, having retention times of 1,5-di-*O*-acetyl-2, 3,4-tri-*O*-methylfucitol, and 1,2,5-tri-*O*-acetyl-3,4 tri-*O*-methylgalactitol. Further analysis of the ch matogram suggested this structure for oligosacchari I: *O*-α-L-fucopyranosyl-(1→2)-*O*-β-D-galactopyranosyl-(1→3)-2-deoxy-2-acetamido-D-galactitol. cubation of oligosaccharide II with β-galactosidase furnished galactose and *N*-acetylgalactosaminitol. Periodate oxidation of the disaccharide followed by sodium borohydride and mild acid hydrolysis led to total destruction of the galactose. The structure of oligosaccharide II was proposed to be *O*-β-D-galactopyranosyl-(1→3)-2-deoxy-2-acetamido-D-galactitol. When the intestinal glycoprotein was subjected to acetolysis and fractionation, the front peak contained high-molecular weight material; the middle one, oligosaccharides and glycopeptides; and the last peak, mostly monosaccharides. When the middle fraction was further fractionated, a disaccharide consisting of galactos and *N*-acetylglucosamine (oligosaccharide III) was present, in addition to other compounds. Oligosaccharide III was methylated, hydrolyzed, and the two component sugars were converted into their ald tol acetates and analyzed by gas-liquid chromatogra phy-mass spectrophotometry, suggesting the following structure for oligosaccharide III: *O*-β-D-galactopyranosyl-(1→4)-2-deoxy-2-acetamido-D-glucose. The results suggest that the molecular co stitution of the germfree rat intestinal mucus does not differ basically from that of other mucus glyco proteins.

8589 SECRETION OF PROTEOLYTIC ENZYMES FOLLOWI INTRODUCTION OF NUTRIENTS INTO THE DUODE AND JEJUNUM.

GENERAL

2 VALUE OF THE NEW EX VIVO "GASTRIC CHAMBER" TECHNIQUE IN STUDYING THE FRAGILITY OF THE GASTRIC MUCOSA. (Fre.) Labrid, C.; Dureng, G.; ro, Ch. (Departement de Pharmacodynamie, C.E.R.M., te de Marsat, 63201 Riom, France). *C. R. Soc. l. (Paris)* 169(3):566-573; 1975.

odification of the gastric chamber technique was d to estimate gastric mucosal fragility. Wistar s were laparotomized, a plexiglas chamber was erted between the pylorus and the distal esopha-, and hemostasis was secured. The mucosal effect perfusing a pH 2.8 disodium citrate-hydrochloric d mixture was not significantly different from t of a pH 2.0 potassium chloride-hydrochloric acid ture, and the effect of a pH 4.2 disodium citrate-rochloric acid mixture was not different from t of a neutral solution. A pH of 1.4 was unsuit-e. The outcome of phenylbutazone (PHB) pretreat-t (12.5-100 mg/kg, p.o.) was measured 30 min er administration. The effect of the pH 2.8 fusate was exacerbated by PHB. Neither the pH perfusate nor PHB (50 or 100 mg/kg) alone signif-ntly affected the gastric mucosa. A combined atment, however, elicited a significantly in-ased mucosal fragility (p=0.05). When PHB was ad-istered 6 hr before perfusion, maximum fragility achieved with the pH 2.8 perfusate; at 24 hr, re was no significant effect. These results con-m that PHB ulcerigenicity is not due to increased d secretion but rather to decreased mucosal re-tance.

)3 THE VALUE OF THERMOCOUPLE IN THE MEASURE-MENT OF THE GASTRIC MUCOSAL BLOOD-FLOW. INFLUENCE OF THE OCCLUSION OF THE CELIAC ARTERY) PROSTAGLANDIN E_1 ON THE GASTRIC MUCOSAL BLOOD W. AN EXPERIMENTAL STUDY IN ANIMALS. (Ger.) ch, H.; Demling, L. (Med. Klinik und Poliklinik Universitat, Postfach 3560, D-8520 Erlangen, W. rmany). *Res. Exp. Med.* 167(1):71-84; 1976.

relation between reduced gastric mucosal blood w and ulcer etiology, the extent of celiac artery constriction and perfusion or secretion in gastric mucosa, and the extent of prostaglandin E_1 impairment of celiac artery flow and its effect on gastric mucosa and secretion are examined. Thermocouples were inserted into the stomachs of hybrid cats at the level of the angle and were fixed to the anterior wall. Pentagastrin administration induced an average blood flow increase of 23-60%; according to increasing intake pressure, the increase occurred equally in the anterior and posterior walls and the two curvatures. All five measurement variables recorded the elevation within the 1st hr; within 30 min of supplementary vasopressin infusion, arterial blood flow registered an additional significant increase ($p<0.005$), while heat conduction ($p<0.05$), aminopurine clearance ($p<0.005$), volume of gastric secretion, and H^+-output ($0.05>p>0.01$) fell significantly. Partial constriction of the celiac artery led to proportional decreases in mucosal perfusion, as measured by all variables except volume and H^+-output, which were unaffected. Supplementary prostaglandin E_1 infusion (2 μg) induced significant increases in blood flow ($p<0.005$), which never returned to pre-prostaglandin E_1 levels after its interruption, and in gastric volume and H^+-secretion. Blood flow, volume, and H^+-output fell after 4 μg prostaglandin E_1; after 8 μg, blood flow increased slightly, and heat conduction, volume, and H^+-secretion decreased. The demands of ulcer therapy, inhibition of acid secretion and promotion of mucosal circulation, are not satisfied by prostaglandin E_1.

8594 ENTEROHEPATIC CIRCULATION OF INDOMETHACIN AND ITS ROLE IN INTESTINAL IRRITATION. (Eng.) Duggan, D. E.; Hooke, K. F.; Noll, R. M.; Kwan, K. C. (Merck Inst. Therapeutic Res., West Point, PA 19486). *Biochem. Pharmacol.* 25:1749-1754; 1975.

The accumulative biliary secretion of indomethacin and its conjugate(s), based on biliary clearance constants and areas under portal and peripheral plasma profiles, was determined in rats, guinea pigs, dogs, rabbits, and spider monkeys, and was estimated for man. ^{14}C-labeled indomethacin, desmethylindomethacin, desbenzoylindomethacin, and desmethyl desbenzoyl indomethacin were administered i.v. in the laboratory animals, and the plasma, biliary, and renal clearances were determined. The accumulative biliary secretion of indomethacin and its conjugates ranged approximately 30-fold, being 13% of the total dose in the rabbit, 21% in the guinea pig, 26% in the monkey, 134% in the rat, and 362% in the dog. This percentage provided a quantitative correlate to the wide species variation in sensitivity to indomethacin-related intestinal lesions; the minimum toxic dosages in rabbits, guinea pigs, monkeys, rats, and dogs were 20.0, 6.0, 1.0, 0.75, and 0.5 mg/kg/day, resp. Extrapolation of the accumulative biliary secretion of indomethacin and its conjugates versus the intestinal toxicity relation to man predicted a therapeutic ratio of approximately 20:1 with respect to intestinal irritation. The pharmacokinetic modeling derived for the present purpose should be of general utility in the quantitation of enterohepatic recycling of drugs or metabolites whose loci of intended or untoward effects include the liver or gut.

8595 MEASUREMENT OF LIVER BLOOD FLOW BY MEANS OF A SINGLE INJECTION OF BROMOSULPHTHALEIN, WITHOUT HEPATIC VENOUS CATHETERIZATION.

(Eng.) Clarkson, M. J.; Hardy-Smith, A.; Richards, T. G. (Liverpool Sch. Tropical Medicine, Pembroke Place, Liverpool L3 5QA, England). 51(2):141-150; 1976.

A method for the measurement of hepatic blood flow without catheterizing the hepatic vein is described. BSP is injected in a single dose and the time course of disappearance of the indicator from the circulation is analyzed. The method was tested in a physical model with a hemodialyzer, in dogs and in turkeys. The mean hepatic plasma flow in 10 anesthetized dogs was 30.7 ml/min/kg, which did not differ significantly from the flow rate determined by the classical Fick method (29.4 ml/min/kg). Since the mean packed cell volume of the blood from the dogs was 46.9, the mean hepatic blood flow was calculated to be 57.8 ml/min/kg. Among 15 unanesthetized turkeys, the mean hepatic plasma flow was 17.8 ml/min/kg, as determined by both methods. The mean packed cell volume was 42.5, so that the mean hepatic blood flow in the turkey was 31.0 ml/min/kg. The correlation coefficient for the new method and the Fick method in all test systems was 0.96. The method has been used in a variety of avian and mammalian species including man, and its use in physiological studies and in clinical medicine is suggested.

8596 BLOOD FLOW IN THE SMALL INTESTINE OF CAT AND MAN AS ANALYZED BY AN INERT GAS WASHOUT TECHNIQUE.

(Eng.) Hulten, L.; Jodal, M.; Lindhagen, J.; Lundgren, O. (Dept. Surgery II, Univ. Goteborg, Goteborg, Sweden). *Gastroenterology* 70 (1):45-51; 1976.

A recently developed ^{85}Kr elimination technique was used to study small intestinal blood flow and flow distribution in cats and in humans undergoing laparotomy for colonic cancer, ulcerative colitis, or Crohn's disease. In the cat at rest, the musculari blood flow was estimated at 14 ml/min/100 g, and the total venous outflow was estimated at 28 ml/min 100 g. The mucosal-submucosal blood flow amounted to 37 ml/min/100 g. It was calculated that 20% of the total blood flow was distributed to the muscula is and about 80% to the mucosal-submucosal layer. In the human studies, the jejunal blood flow was 44 ml/min/100 g, the ileal blood flow was 34 ml/min 100 g, and the total small intestinal blood flow wa 38 ml/min/100 g. The jejunal muscularis flow was 23 ml/min/100 g, and the ileal muscularis flow was 20 ml/min/100 g. The blood flow to the mucosa-submucosa was 61 ml/min/100 g. Flow distribution calculations revealed that 75% of the total blood flow was distributed to the mucosa-submucosa and 25% to the muscularis. The quantitative and qualitative similarities between feline and human intestinal ci culation are stressed.

8597 CHANGES IN THE BLOOD SUPPLY OF THE GASTRO INTESTINAL TRACT IN RATS WITH AGE.

(Eng. Varga, F.; Csaky, T. Z. (Medical Univ. Pecs, H-7640 Pecs, Hungary). *Pfluegers Arch.* 364(1);129-133; 19

To determine whether a blood supply gradient exists from the oral to the aboral end of the small intestine, regional blood flow of the gastrointestinal tract and cardiac output were determined in male Sprague-Dawley rats (30-726 g). The cardiac output was determined in 81 rats weighing 60-642 g. The body weight of the animals correlated with age, except in those weighing 500 g or more. Cardiac output in the 81 rats decreased with age in relativ value. An inverse linear relation was obtained between the logarithm of the cardiac output per kil gram body weight and the logarithm of the body weig The total wet weight of the alimentary tract was 5. of the body weight in 20- to 21-day-old rats and 6. in 25- to 28-day-old rats; the proportion declined larger animals, e.g., 1.95% in rats weighing 566 g. The fractional blood flow of the total gastrointestinal tract was highest in 20- to 21-day-old rats (21% of the total injected ^{86}Rb); this decreased markedly with age. During the weaning period, the blood flow to the fore and glandular stomach was significantly lower ($p<0.05$) than that to the distal parts of the gastrointestinal tract. There was no significant difference in the fraction blood flow of the small intestine, cecum, and large intestine in rats with an average body weight of 37.7 g. In rats weighing 65 g, the fractional bloo flow of the small intestine was 4.38%. This was significantly higher than that of the cecum (3.17%) but it did not differ significantly from the fractional blood flow of the large intestine (3.79%). In rats weighing 90 g or more, the fractional blood flow of both the cecum and the large intestine was significantly less than that of the small intestine There was no blood supply gradient within the small intestine of rats weighing 65 g or less. Such a gradient in the blood supply developed progressivel with age, and in rats age 6 months or older, the blood flow was significantly lower in the ileum tha in the jejunum.

98 EFFECT OF FASTING ON MUCOSAL BLOOD FLOW IN ANTRUM AND CORPUS OF THE STOMACH. (Eng.)

ylor, T. V.; Pullan, B. R.; Torrance, H. B. (Man-
ester Royal Infirmary, Manchester M13 9WL, England).
r. *Surg. Res.* 8(3):227-235; 1976.

stric mucosal blood flow rates for the antrum and
e corpus were studied in Wistar rats by means of
e ^{86}RbCl clearance technique, and the effects of
sting, food intake, and vagotomy on these flow
tes were determined. Directly after a meal, there
s a threefold increase in both antral and corpus
ow rates, the antral rate increasing from 3.24 to
.21 flow units and the corpus rate increasing from
35 to 7.09 flow units. With progressive fasting up
48 hr, there was a decrease in the mucosal perfu-
on to both antrum and corpus, the diminution of the
tral flow rate being more marked than that of the
rpus flow rate. In vagotomized animals, feeding
oduced a smaller increase in the mucosal flow to
th antrum and corpus: 8.01 flow units for the an-
um and 6.85 flow units for the corpus. It is sug-
sted that the antrum plays an active role in the
sponse to a physiological stimulus and may contri-
te to the control of parietal cell blood flow and
cretion.

99 KINETICS OF ESTABLISHING HUMAN FECAL FLORA IN GERM-FREE MICE AND TRIAL OF DECONTAMINA-
ON BY ANTIBIOTHERAPY. (Fre.)

Ghnassia, J. C.;
ron, M.; Ducluzeau, R.; Muller, M. C.; Raibaud, P.
aboratoire de Bacteriologie, Faculte de Medecine,
cker-Enfants Malades, 75730 Paris Cedex 15, France).
n. *Microbiol. (Paris)* 126(3):367-379; 1975.

attempt was made to establish an equilibrium of
e bacterial strains isolated from the gastrointes-
nal tract of a child in a plastic isolator in gno-
xenic C3H strain mice and to render the mice axenic
antibiotics. The bacterial strains (and the day
p.o. administration) included *Acinetobacter lwoffi*
), *Staphylococcus epidermidis* (7), *Clostridium*
rfringens (21), *Plectridium anatum* (54), *Strep-*
coccus bovis (54), *Corynebacterium* (54), *Bacillus*
cheniformis (109), and *Enterobacter cloacae* (122).
lwoffi proliferated in 24 hr from 10^5/g to 10^7/g.
epidermidis was established at a high level and
creased rapidly from 10^8/g to 10^4/g. The remain-
g strains remained relatively constant. At the
d of 6 weeks, *C. perfringens* was the dominant
ora (10^9/g), *P. anatum* was 10 times less abundant,
d *S. bovis* and the *Corneybacteria* were 100 times
ss abundant. Four of the six other strains disap-
ared within 24 hr of *B. licheniformis* and bacitra-
ne inoculation, except for low levels of *A. lwoffi*
d *S. epidermidis*. *B. lichenformis* became the domi-
nt flora. At day 116, *P. anatum* and *S. bovis*
appeared. At day 122, *E. cloacae* was injected
to the mice; it rapidly became the dominant flora
0^9/g), without altering the equilibrium, by arrest-
g bacitracine production. At day 198, the equilib-
um conditions in the mice were equivalent to those
the infant for *C. perfringens*, *P. anatum*, *E. cloa-*
e, and *S. bovis*. At sacrifice on day 292, the
ssue distributions (in log numbers of bacteria
r gram of organ) in the stomach, small intestine, cecum, and colon, resp., were 3, 5.3, 8.9, and 8.6 for *P. anatum;* 3.9, 5.3, 8.3, and 8.5 for *B. licheniformis;* and 6.6, 6.6, 8.8, and 9.2 for *E. cloacae*. Gnotoxenic mice proved to be a good experimental model because their bacterial equilibrium was comparable to that of the gastrointestinal tract of the child raised in a plastic incubator.

8600 THE PHARMACOLOGY OF ANAPHYLAXIS IN THE CHICKEN INTESTINE. (Eng.)

Chand, N.; Eyre, P. (Dept. Biomedical Sciences, Univ. Guelph, Guelph, Ontario N1G 2W1, Canada). *Br. J. Pharmacol* 57(3):399-408; 1976.

The Schultz-Dale reaction was investigated in circular smooth muscle strips of esophagus, crop, duodenum, jejunum, and ileum from actively sensitized chickens. To illustrate the possible nature of the principal chemical mediator(s) participating in anaphylaxis in the chicken intestine, known specific antagonists, together with nonsteroidal anti-inflammatory agents and some new anti-anaphylactic drugs, were included in the study. The chickens were sensitized either to bovine albumin or to horse plasma. All strips contracted in response to acetylcholine (threshold dose 10^{-10}-10^{-7} M); histamine (10^{-7} -10^{-4} M); 5-hydroxytryptamine (10^{-10}-10^{-4} M); prostaglandins E_1, E_2, and F_2; bradykinin, and bovine slow reacting substance of anaphylaxis (SRS-A). Marked seasonal and individual variations in the responsiveness of gut tissues to these exogenous agonists were noted. Tissues were measurably more sensitive to agonists in the spring and summer than in winter. Mepyramine (0.5-1.0 μl/mg) inhibited the contractions in the ileum, suggesting the existence of H_1-histamine receptors. Methysergide (0.2 and 2.0 μg/ml) blocked 5-hydroxytryptamine-induced contractions, demonstrating the preponderance of "D"-musculotropic tryptamine receptors. The failure of the selective receptor antagonists of acetylcholine, histamine, and 5-hydroxytryptamine (atropine, mepyramine, and methysergide) to modify the Schultz-Dale reaction suggested that aminergic mechanisms are not involved in this reaction. Partial to complete blockade of the Schultz-Dale reaction by a prostaglandin receptor antagonist (polyphloretin phosphate, PPP); prostaglandin synthetase inhibitors (sodium meclofenamate and phenylbutazone); inhibitors of synthesis and release of histamine and SRS-A [5,5-dimethyl-11-oxo-5H, 11H-(2)-benzopyrano(4,3-g)(1)benzopyran-9-carboxylic acid ethanolamine salt; 2-9-propoxyphenyl-8-azapurin-6-one; diethylcarbamazine citrate, and PPP] and an inhibitor of proteinases (apoprotein) strongly suggested the involvement of vasoactive lipids and polypeptides in the anaphylactic response of chicken ileum to specific antigen.

8601 EVOLUTION OF HYPERPLASIA, HYPERPLASTIC NODULES, AND CARCINOMAS OF THE LIVER INDUCED IN RATS BY N-2-FLUORENYL-DIACETAMIDE. (Eng.)

Reuber, M. D. (National Cancer Institute, Bethesda, MD 21044). *Gann Monogr. Cancer Res.* 17:301-342; 1975.

The results of studies on the evolution of hyperplasia, hyperplastic nodules, and liver carcinomas induced in rats by treatment with 0.025% *N*-2-fluorenyldiacetamide (FdiAA) are presented, together with a series of 68 histologic photographs. Eight to sixteen weeks of treatment with the carcinogen induced hyperplasia of the liver cells. If the carcinogen-containing diet was discontinued after 8 weeks of feeding, the hyperplastic foci disappeared within the 65-week observation period. If the treatment was continued for longer periods, hyperplasia began to appear as nodules of hyperplasia. Only a few areas progressed to nodules, whereas most developed degenerative changes in the cytoplasm. These nodules either remained as nodules or progressed to carcinomas and did not disappear or undergo diffuse degenerative changes. Hyperplastic nodules continued to grow, even though the carcinogenic stimulus was discontinued. The longer the feeding period, the faster the nodules grew. Areas of hyperplasia did not survive on transplantation to any site in an isologous host. Hyperplastic nodules survived and increased in size only following intrahepatic transplantation to isologous hosts. The cells eventually developed degenerative cytoplasmic changes and did not progress to carcinoma. Transplanted carcinomas of less than 5 mm that had well differentiated cells progressed to well differentiated carcinomas only in the liver in which they developed; when transplanted to the liver of isologous hosts, they grew only as small hepatocellular carcinomas. Small carcinomas with poorly differentiated cells grew both autologously and isologously in the spleen, muscle, and subcutaneous tissue. Carcinomas 1.0 cm or larger either remained the same size or increased when transplanted in the liver, lungs, spleen, peritoneum, muscle, and subcutaneous tissues. Undifferentiated large carcinomas grew rapidly, whereas well-differentiated carcinomas grew slowly, and the growth of poorly differentiated carcinomas was intermediate. The transplantable carcinomas grossly and microscopically resembled the primary carcinomas in early generation transplants; however, in later generation transplants, the morphology and growth rates of well differentiated carcinomas resembled those of poorly differentiated carcinomas. Cirrhosis appeared at the same time as areas of parenchymal cell hyperplasia and progressed during the period of carcinogen feeding. After withdrawal of the carcinogen, the same hyperplastic lesions continued to progress, whereas the cirrhotic changes regressed and at death were often minimal and focal. In the progress of neoplasia, there is a gradual transition from the state of dependency toward one of autonomy.

8602 HEPATOMA, HOST LIVER, AND NORMAL RAT LIVER PHOSPHOLIPIDS AS AFFECTED BY DIET. (Eng.)

Wood, R. (Univ. Missouri Sch. Medicine, Columbia, MO 65201). *Lipids* 10(12):736-745; 1975.

Individual phospholipid classes derived from hepatoma 7288CTC, normal rat liver, and host liver of animals maintained on chow and fat-free diets were examined in detail, and the sphingomyelin and phosphoglyceride structures were compared. The percentages of most phospholipid classes in normal and host livers were essentially the same, and diet had little or no effect. Host livers from rats on the fat-free diet contained about 50% or less phosphatidylcholine (PC), phosphatidylinositol (PI), phosphatidylserine (PS), and diphosphatidylglycerol (DPG) than did normal livers of animals on both diets and host livers of chow-fed rats. Hepatoma sphingomyelin (SPH) concentrations (14.5% in chow-fed, 17.7% in fat-free diet-fed animals) were higher than those in the other groups (3.1, 3.2, 4.6, and 4.0% in normal livers of chow-fed rats, normal livers of fat-free, host livers of chow-fed, and host livers of fat-free rats, resp.). The concentrations of all other phospholipid classes [PC, PI, PS, DPG, phosphatidylethanolamine (PE), and lysophosphatidylcholine (Lyso-PC)] were lower in the hepatomas than in the other groups Hepatoma PC and PE concentrations were only 25 and 50% of liver levels, resp. The 1-position of all hepatic PC exhibited the same fatty acid composition 41% was composed of 16:0, and 56.6% was composed of 18:0. Host and normal liver PE were similar at the 1-position and contained primarily palmitate and stearate. The 1-position of hepatoma PE, affected little by diet, contained only 25-35% as much palmitate as liver PE. Polyunsaturated fatty acids dominated the 2-position of PC and PE of livers, but not of the hepatoma. Generally, the 2-position of PC and PE in host and normal liver from animals on the same diet was similar. However, the fat-free diet reduced the percentage of 18:2 in liver DPG 3-fold, and the decrease was offset by increased percentages of 16:1 and 18:1. The low percentage of 18:2 in hepatoma DPG was offset by increased percentages of 18:0 and 16:0. Liver PI and PC from the rats fed the fat-free diet contained the highest percentage, 20:3, which replaced 20:4. Hepatoma SPH contained a higher concentration of 24:0 and 24:1 than liver. The SPH also contained a C-24 dienoic acid, which was not detected in host and normal liver. Host liver contained a higher percentage of 22:6 than normal liver. Diglycerides derived from host liver PC contained significantly more ^{38}C than normal liver. Diglycerides from hepatoma PC and PE exhibited a 1-random-2-random distribution of fatty acids, whereas diglycerides from liver PC and PE showed pairing of specific fatty acids.

8603 CHOLESTATIC EFFECTS OF Escherichia coli ENDOTOXIN [sic] ENDOTOXIN ON THE ISOLATED PERFUSED RAT LIVER. (Eng.)

Utili, R.; Abernathy, C. O.; Zimmerman, H. J. (First Medical Sch., Univ. Naples, Naples, Italy). *Gastroenterology* 70(2): 248-253; 1976.

The effects of *Escherichia coli* endotoxin on the rates of bile flow and dye excretion were studied in isolated rat livers. At 0.5 mg/100 ml, endotoxin did not affect the rate of bile flow, but at 1 and 2 mg/100 ml, the rate was reduced by 18 and 27%, resp. Clearance of BSP was significantly reduced by 0.5 mg/100 ml, when dye excretion was expressed on the basis of liver weight ($p<0.05$), and the half-life of BSP in the perfusate was increased by 25%. At 1 mg/100 ml, endotoxin reduced BSP excretion even more ($p<0.001$), and this effect was greater with 2 mg/100 ml. The half-life of BSP was increased by and 64%, resp., by 1 and 2 mg of endotoxin/100 ml. e perfusate flow rate was decreased 6-8, 16, and %, resp., by 0.5, 1, and 2 mg endotoxin/100 ml. chanical reduction of the perfusate flow rate did t significantly decrease BSP excretion. The amount indocyanine green excreted by the perfused livers s significantly decreased when the perfusate con- ined 1 mg endotoxin/100 ml ($p<0.001$), but the half fe of this dye was not affected. At 0.5 and 1 mg/ 0 ml, endotoxin did not affect the release of GOT om the perfused livers, but a significant increase <0.05) occurred with 2 mg/100 ml. The release of T was not affected by any of the concentrations of dotoxin. The exposure of isolated hepatocytes to dotoxin (0.5-5 mg/100 ml) did not result in any akage of GOT from the cells. Kinetic data sugges- d that the effects of endotoxin were on the cretory mechanisms of the hepatocyte.

504 PORTAL HYPERTENSION AND GASTRIC LESIONS IN THE RAT. (Eng.) Phelps, T. O.; Mul- ane, J. F. (Dept. Biological Sciences, Wright tate Univ., Dayton, OH). *Arch. Surg.* 111(2):190- 94; 1976.

e effect of portal hypertension without jaundice the incidence of spontaneous and restraint-induced astric lesions was studied in rats. Portal vein onstriction (PVC) was accomplished by ligating the ortal vein against a hypodermic needle, which was hen removed. Measurements were carried out 2, 4, 7, nd 14 days after surgery in PVC and sham-operated nimals. Restrained animals were confined in wire esh sheets for 7 hr. Unrestrained rats with portal ypertension of 4 days' duration had a higher inci- ence of grade 1 lesions than did sham-operated rats. estrained PVC rats had a higher incidence of grade and 2 gastric lesions at 2, 4, and 7 days than did estrained sham-operated animals. Vagotomy and yloroplasty performed at the time of PVC protected he stomach from forming gastric lesions associated ith stress ($p<0.05$ for both grade 1 and 2 lesions). ortal pressures were significantly higher in rats ith PVC than in sham-operated rats immediately $p<0.001$) and at 4 days ($p<0.001$), while the portal ressures of the two groups were similar at 7 and 4 days postoperatively. SGOT and blood ammonia ere significantly increased ($p<0.01$ and 0.02, resp.) n PVC rats, but serum bilirubin and alkaline phos- hatase levels were similar in the two groups. Pro- hrombin time, partial prothrombin time, and fibri- ogen were not statistically different on the 4th ay, but the platelet count was significantly dec- eased in PVC rats ($p<0.001$) and in PVC-splenectom- zed rats ($p<0.05$). Gastric luminal oxygen pressure as decreased on day 2 after PVC, but was normal hereafter. PVC rats had a postoperative respiratory lkalosis. Four days after surgery, the gastric ecretion volume, acid concentration, and total acid ontent were similar in both PVC and sham-operated nimals. Except for venous congestion in rats with ortal hypertension, sham and PVC rats had similar orphology of the gastric epithelium in noneroded reas. PVC rats gained less weight than sham- perated rats. It is concluded that gastric conges- ion, weight loss, and possibly portasystemic shunting contributed to the higher incidence of gastric erosions with portal hypertension.

8605 A NEW MODEL OF STRESS ULCER IN THE RAT WITH PYLORUS LIGATION AND ITS PATHOGENESIS. (Eng.) Takeuchi, K.; Okabe, S.; Takagi, K. (Dept. Chemical Pharmacology, Univ. Tokyo, 7-3-1 Hongo, Bunkyo, Tokyo, Japan 113). *Am. J. Dig. Dis.* 21(9): 782-788; 1976.

Stress ulcers were produced in intact and pylorus-ligated male Donryu rats by water immersion stress, and the effects of various drugs and vagotomy on the newly developed ulcers were examined to clarify the mechanisms of formation. In intact rats immersed in water for 7, 14, or 20 hr, elongated ulcers, varying between 2 and 12 mm in length, or punctate ulcers developed only in the corpus. The mean ulcer index was highest after 7 hr of stress (59.9). When the pylorus was ligated prior to stress, the ulcers occurred in both the corpus and the antrum, and the morphological features were altered. The lesions were multiple, punctate, and superficial. The rhombic-shaped lesions that developed in the proximal antrum revealed a high incidence (50-70% of stressed, pylorus-ligated animals) of penetration into the muscularis mucosa. In the pylorus-ligated rats, the development of ulcers increased with time. After more than 14 hr ligation, several gastric Shay ulcers occurred in the forestomach in both normal and stressed rats. Gastric secretion was suppressed in the stressed pylorus-ligated animals. Stress ulcers observed in intact rats were not aggravated by pylorus ligation. The administration of sodium bicarbonate (83.3, 250, and 750 mg/kg, p.o.) and other drugs that reduce gastric secretion, such as chlorpromazine (20 mg/kg, s.c.), hexamethonium (20 and 40 mg/kg, s.c.), atropine (5 and 15 mg/kg, s.c.), and metiamide (12.5, 50, and 100 mg/kg, i.p.) inhibited the development of stress ulcers in pylorus-ligated rats. Inhibition by sodium bicarbonate was 49.5, 83.6, and 99.7% at the doses given, resp.; by chlorpromazine, 95.8%; by hexamethonium, 54.6 and 87.5%, resp.; by atropine, 98.2 and 100%, resp.; and by metiamide, 34.9, 69.1, and 74.9%, resp. Bilateral vagotomy also decreased the incidence of ulcers by 92.4%. The administration of amylopectine sulfate (100 or 200 mg/kg) reduced gastic acidity and peptic activity and changed the punctate stress ulcers to elongated lesions. A voluminous precipitate observed in the gastric contents suggested that amylopectine might combine with some mucosal substance and remove it from the gastric surface into the lumen under stress. Thus, the lowered function of so-called mucosal defensive factor appeared to contribute to the pathogenesis of amylopectine-induced ulcers. This model appears to be useful in the study of peptic ulcer diseases.

8606 FOREIGN SERUM-INDUCED PANCREATITIS IN MICE. I. A NEW MODEL OF ACUTE PANCREATITIS. (Eng.) Janigan, D. T.; Nevalainen, T. J.; MacAulay, M. A.; Vethamany, V. G. (Dept. Pathology and Anatomy, Dalhousie Univ., Halifax, Nova Scotia, Canada). *Lab. Invest.* 33(6):591-607; 1975.

The chance observation that acute pancreatitis rapidly develops in mice after the i.p. injection of fresh human, sheep, or rabbit serum is reported. Within 1-2 hr after one injection of fresh human serum by the intraperitoneal route only, male C57BL/10J mice developed pancreatic acinar cell necrosis and inflammation, fat necrosis, elevated serum amylase, and a shocklike state. The extent of these lesions and mortalities was roughly dose-dependent (0-1.5 ml human sera) and was not noticeably modified by either different fasting cycles or pilocarpine. Acinar cell changes and necrosis usually developed first in subserosal acini. The earliest ultrastructural change detected was nonspecific swelling of cytoplasmic compartments, which was reversible but also preceded the cytoplasmic degradation that developed in cells undergoing necrosis. Notably, zymogen granule dissolution neither preceded nor accompanied this swelling, but developed *pari passu* with cell degradation. Serum was cytotoxic for isolated acinar cells *in vitro*, even in the presence of soybean trypsin inhibitor. These results indicate that the injury mechanism *in vivo* is directly initiated through contact of serum with acinar cell surfaces and is independent of zymogen secretions and trypsin activation. They suggest that a rapid disturbance in cell membrane permeability results, the magnitude of which being the primary determinant of cell death. Pancreatic toxicity of human serum was abolished by aging, heating, EDTA, heparin, zymosan, cobra venom factor, and absorptions with mouse RBC against which fresh, unabsorbed serum was hemolytic. Pancreatic toxicity *in vitro*, and to a much lesser extent *in vivo*, was reconstituted by combining the RBC-absorbed serum with either heated serum, or with immunoglobulin M (IgM)-enriched, but not IgG serum fractions. Fresh cord serum was virtually nontoxic and could substitute for absorbed serum in such reconstitutions. These results indicate that the injury mechanism involves at least two serum components. Other results and a review of other examples of foreign sera toxicity suggest that they are components of a complement-dependent, cytotoxic heterophile antibody system. This phenomenon offers a simple model of acute pancreatitis, contributes to the debunking of traditional notions of the pivotal role of zymogens in the initiation of acute pancreatitis, and hints at a potential pathogenetic connection between pancreatitis and products of immune or related reactions.

8607 HEPATIC FUNCTIONAL DETERIORATION AFTER PORTACAVAL SHUNT IN THE RAT. EFFECTS ON SULFOBROMOPHTHALEIN TRANSPORT-MAXIMUM, INDOCYANINE GREEN CLEARANCE AND GALACTOSE ELIMINATION CAPACITY.

(Eng.) Lauterburg, B. H.; Sautter, V.; Preisig, R.; Bircher, J. (Dept. Clinical Pharmacology, Univ. Berne, Berne, Switzerland). *Gastroenterology* 71(2): 221-227; 1976.

The consequences of portacaval shunt on metabolic and excretory liver function were studied 12-16 days following end-to-side portacaval anastomosis in male Sprague-Dawley rats. Fourteen days after the procedure, the galactose elimination capacity (GEC) and the plasma clearance of indocyanine green (ICG) were reduced in proportion to the approximately 50% loss in liver mass; the mean control liver weig GEC, and ICG clearance were 4.0-4.2 g/100 g, 2.30-2.52 μmol/min/100 g (or 0.58-0.61 μmol/min/g liver) and 0.84 ml/min/100 g (or 0.21 ml/min/g liver), res The biliary transport maximum for BSP decreased by almost 70%, from 153 to 52 nmol/min/100 g after por caval anastomosis. This reduction was accompanied by a significant decrease in the hepatic conjugatio of the dye to glutathione. These results demonstra that a quantitative and qualitative functional deterioration of previously normal livers results from portal blood deprivation.

8608 ESOPHAGEAL, GASTRIC AND DUODENAL MUCOSA POTENTIAL IN THE NORMAL SUBJECT. (Ita.)

(Abteilung Gastroenterologie und Stoffwechselerkrankungen, Medizinische Klinik und Poliklinik der Universitat, 3400 Gottingen, Humboldtallee 1, W. Germany). *Dtsch. Med. Wochenschr.* 101 (10):353-360; 1976.

The role of the oral ^{14}C-glycocholate breath test (GBT) in detecting the cause of diarrhea and steatorrhea in syndromes with increased bacterial deconjugation of bile acids was examined. In 15 patients without gastrointestinal disease, the GBT was normal. In 2 of 2 ileus cases, 8 of 12 diabetic neurogastroenteropathies, and 4 of 4 scleroderma patients, however, the test was abnormal (elevated $^{14}CO_2$). The ratios after various surgical corrections were as follows: gastric resection (Billroth II), 13 of 24; total gastrectomy, 4 of 4; duodenopancreatectomy, 5 of 5; small and large bowel fistulation, 9 of 12; afferent loop syndrome, 1 of 1; duodenal diverticulitis, 1 of 2; ileum resection (<100 cm), 6 of 8; ileum resection (>100 cm), 5 of 5; and colectomy, 0 of 3. In chologenic and other diarrheas, the following were found: *Salmonella* enteritis, 0 of 1; laxative abuse, 0 of 1; nonspecific enteritis, 1 of 2; irritable colon syndrome, 1 of 6; Whipple's disease, 0 of 2; sprue, 0 of 7; Crohn's disease, 6 of 12; ulcerative colitis, 0 of 7; intestinal amyloidosis, 1 of 1; Verner-Morrison syndrome, 1 of 1; and pancreatic insufficiency, 0 of 9. Excluding the normal group, the total quotient was 68 of 134. The site of bile acid deconjugation can be predicted by determining the delay time in reaching maximal expiratory levels.

8629 STUDIES OF THE DIAGNOSTIC AND PROGNOSTIC POTENTIAL OF IMMUNOLOGICAL TESTS FOR ECHINOCOCCOSIS. (Ger.) Todoroff, T.; Yurukova, D. (Medizinische Akademie, Lehrstuhl fur Epidemiologie und Parasitologie, Sofia 31, Bulgaria). *Zentralbl. Bakteriol.* [*Orig. A*] 228(3):402-413; 1974.

The diagnostic and prognostic value of complement fixation, indirect hemagglutination, and latex agglutination in echinococcosis infection was assayed. Sera from 118 affected patients was drawn preoperatively and in 22 cases, 10-32 months postoperatively. The highest percent of positive sera was harvested by indirect hemagglutination (88%), followed by latex agglutination (85%), and complement (81%). Positive results with liver echinococcosis were significantly higher than in lung echinococcosis. Indirect hemagglutination was 97% sensitive to liver echinococcosis, with complement fixtation at 87% and latex agglutination at 88%. In specificity tests in 97 healthy persons, all sera showed negative latex agglutination and indirect hemagglutination, and 4 were weakly complement fixation positive; the nonspecific complement fixation reaction impairs its diagnostic value. The three tests correlated qualitatively in 75.5-82.3% of the positive and 6.8% of the negative results. The highest positive correlation was in liver infection (85.7%). Paired correlations found latex agglutination and indirect hemagglutination at 72.2%, complement fixation and latex agglutination at 53.4%, and complement fixation and indirect hemagglutination at 47.5%. The quantitative correlation between indirect hemagglutination and latex agglutination was higher than that between the three values. All secondary echinococcoses reacted positively to the tests. The average values were five times higher in complement fixation and six to eight times higher in indirect hemagglutination and latex agglutination than with primary infection, probably due to secondary antibody formation. Postoperative followups found a decrease in titer or disappearance of antibodies in 18 of 22 patients. By immunologic examination of the postoperative development of the disease, a prognosis may be given by estimating the persistance, decrease, or disappearance of antibody during the postoperative period.

8630 ACCIDENTS DUE TO DUODENOSCOPIC CATHETERIZATION OF THE AMPULLA OF VATER. NATIONAL INQUIRY CARRIED OUT ON 2,819 CASES. (Fre.) Jeanpierre, R.; Gaucher, P.; Laurent, J. X.; Vicari, F.; Heully, F. (CHU, Hopital Brabois, 54037 Nancy Cedex, France). *Ann. Gastroenterol. Hepatol.* 12(3):185-188; 1976.

A statistical survey of accidents due to perduodenoscopy of the ampulla of Vater is reported. There was 113 accidents in 2,819 duodenoscopic catheterizations, and 13 of 113 were fatal. The accidents were caused by premedication (7 cases, 2 deaths), the endoscopic technique (6 cases, 1 death), retrograde cholangiography (52 cases 10 deaths), and wirsungography, which lead to acute pancreatitis (48 cases, 0 deaths). In the premedication cases, neuroleptic analgesia induced respiratory depression plus apnea, leading to rapid collapse in two patients. The endoscope, perhaps stimulating hypotonia, was responsible for six duodenal perforations, five of which were surgically correctable; no gastric or pharyngoesophageal perforations occurred. The majority of the cholangiographic accidents were of infectious origin: simple angiocholitis (40 cases, 3 deaths), icterouremigenic angiocholitis (8 cases, 6 deaths), or cholecystitis (3 cases). In one patient the contrast medium was responsible. The wirsungographi accidents were associated with the host response, leading to elevated urinary and serum amylases and acute pancreatitis. The latter occurred in all 48 of the affected patients; medical correction was possible in 39, but surgical intervention was required in 9. The number of catheterizations and the amount, temperature, concentration, and antibiotic composition of the contrast medium are factors to be considered.

8631 ON THE DYE SPRAYING METHOD IN COLONOFIBERSCOPY. (Eng.) Tada, M.; Katoh, S.; Kohli Y.; Kawai, K. (Kyoto Prefectural Univ., Kawaramachi-Hirokoji, Kyoto, Japan). *Endoscopy* 8(2):70-74; 1976

The diagnostic value of the dye spraying method in colonofiberscopy was assessed in 11 patients with normal colonic mucosa and in 26 patients with ulcer-

ive colitis. Indicarmine or methylene blue was
ed for spraying. In all normal patients in whom
e spraying with indicarmine was undertaken, oval,
indle, or mixed fine mucosal changes were seen;
e spindle form was encountered in 51.8% of the
ses, the oval form in 20.5%, and the mixed forms
27.7%. The spindle forms decreased in frequency
th age, while the mixed and oval forms increased
th age. Endoscopic examinations (101) were under-
ken after dye spraying with indicarmine in 22
tients with ulcerative colitis. In 12 of these
aminations, the stage of colitis was determined
be grade III (course and asymmetrical features
companied by erosions or ulcerations); in 38
aminations, the stage was grade II (irregular
d asymmetrical features without erosion or ulcer-
ion); in 38 cases, the stage was grade I (almost
rmally arranged spindle or oval fine structures,
t sporadic small depressions in the mucosa); and
13 cases, the mucosa was normal. Clinically, all
ses of grade III and 31.6% of the grade II cases
d colitis in the active phase, and the remaining
se had quiecent phase colitis. When 0.1% methyl-
e blue was used for spraying, the degree of stain-
g was correlated with the disease stages. Ninety
rcent of the cases with active disease had unstain-
mucosa, and 57.1% of the cases with active disease
d slightly stained mucosa. Ten percent of the
tients with mucosa in the healing process had
stained mucosa, 42.9% had slightly stained mucosa,
d 26.5% had well stained mucosa; 73.5% of the cases
th normal mucosa had well stained mucosa. Indi-
rmine or methylene blue dye spraying in colonofiber-
opy may be useful in determining the disease stage
ulcerative colitis.

532 EVALUATION OF ESOPHAGEAL TESTS IN THE
DIAGNOSIS OF REFLUX ESOPHAGITIS. (Eng.)
ehar, J.; Biancani, P.; Sheahan, D. G. (Veterans
dmin. Hosp., West Haven, CT 06516). *Gastroenterol-*
gy 71(1):9-15; 1976.

he sensitivity and specificity of each of five
sophageal tests used in the diagnosis of reflux
sophagitis were compared with those of six combin-
tions of two tests, one indicating esophagitis and
he other indicating sphincter incompetence. The
sophageal tests were performed in 77 men with re-
lux symptoms, 11 men with chest pain, and 12 men
nd 1 woman with esophagitis without reflux symp-
oms. The results of the acid infusion test were
ignificantly different from those in normal sub-
ects only in patients with chest pain ($p<0.001$).
ultiple biopsy specimens showed the incidence of
istological abnormalities to be significantly dif-
erent in patients with duodenal ulcer ($p<0.02$) and
eflux symptoms ($p<0.001$) than that in control sub-
ects. The mean resting lower esophageal sphincter
ressure of patients with reflux symptoms was sig-
ificantly lower than that of all other subjects
$p<0.001$). The acid infusion test and esophageal
iopsy combined with esophageal pH study after HCl
eflux showed similar sensitivity to and greater
pecificity than any test alone. The combination
sophageal biopsy with esophageal pH study after HCl
eflux was most sensitive in patients with chronic
reflux symptoms ($p<0.05$), patients with esophagitis without reflux symptoms ($p<0.05$), and duodenal ulcer patients ($p<0.01$). The findings show the limitations of relying on the results of single esophageal tests in patients with symptoms or esophageal findings suggesting reflux esophagitis.

8633 BLOOD XYLOSE TEST IN CHILDHOOD: CORRELATION OF ONE-HOUR BLOOD XYLOSE VALUE TO THE NUMBER OF INTRAEPITHELIAL LYMPHOCYTES IN THE SMALL INTESTINAL MUCOSA IN CELIAC DISEASE. (Ger.) Schaad, U.; Gaze, H.; Hadorn, B.; Pedrinis, E.; Cottier, H.; Lorenz, E.; Colombo, J. P. (Universitats-Kinderklinik, Freiburgstrasse 23, CH-3010 Bern, Switzerland). *Helv. Paediatr. Acta* 30(4/5):331-341; 1975.

The diagnostic value of the 1-hr blood xylose test was examined in terms of the degree of mucosal embarrassment in celiac disease (CD). Venous samples were taken from 59 pediatric patients 1 hr after p.o. administration of D-xylose (5 g). The number of completely intraepithelial lymphocytes per 50 successive epithelial cell nuclei in small bowel biopsy sections was counted. The patient population included four groups: I, florid CD (16 cases); II, treated CD, with gluten-free diet (8 cases); III, clinically unconfirmed suspicion of CD (26 cases); and IV, status not confirmed after clinical diagnosis of CD (9 cases). The difference between the average values of group I and those of groups II, III, and IV was significant ($p<0.001$); groups II, III, and IV varied insignificantly. The correlation of a 1-hr blood xylose level of 20 mg% and the intraepithelial lymphocyte infiltration of 23 of 50 patients was highly significant for group I. No variable, including age and body weight, correlated with xylose level or lymphocyte number in groups II, III, and IV. The blood xylose test has an auxiliary role in establishing indications for intestinal biopsy and remains useful in atypical gastrointestinal clinical pictures or in family studies. It is not an effective diagnostic surrogate for small bowel biopsy in CD.

8634 INTRAVENOUS CHOLANGIOGRAPHY: RECURRING CONCEPTS. (Eng.) Scholz, F. J.; Larsen, C. R.; Wise, R. E. (Lahey Clinic Foundation, 605 Commonwealth Ave., Boston, MA 02215). *Semin. Roentgenol.* 11(3):197-202; 1976.

Techniques and concepts of i.v. cholangiography have been reexamined, and some current views are presented. Nonvisualization of the gallbladder on p.o. cholecystography and the evaluation of symptoms after cholecystectomy are the two most frequent and useful indications for performing i.v. cholangiography. The only absolute contraindication to i.v. cholangiography is a documented hypersensitivity reaction, such as profound or persisting hypotension, usually accompanied by nausea, vomiting, and dyspnea. This reaction occurs in about 1% of patients. Adrenalin (0.3 ml of a 1:1,000 solution, s.c.), diphenhydramine hydrochloride (50 mg, i.v. or i.m.), corticosteroids, and oxygen are administered, and the reaction usually responds promptly with no harm to the patient. Other types of reactions are visceral (nausea, vomiting, and occasional tenesmus) and dermal (pruritus, erythema, and hives). Visceral reactions are probably related to the rate of iodipamide administration and are not true allergic reactions. After a few minutes' delay, resumption of the injection at a slower rate usually permits completion of a satisfactory cholangiogram. The dermal reaction can be minimized or prevented by premedication with an antihistamine. A light breakfast before the administration of iodipamide may lessen the rate and severity of reactions. Good results may be obtained when 20 ml of a 52% solution of iodipamide is injected by hand at an even rate over a 10-min period. The patient is maintained in a 15-degree right posterior oblique position, and films are obtained at 20-min intervals. Toxic effects on the kidney and liver have been noted with iodipamide, and it should be used judiciously in the presence of coexisting renal and liver disease. Opacification of a gallbladder without calculi on i.v. cholangiography may indicate a normal gallbladder, even though the gallbladder failed to visualize on previous p.o. cholecystography. If the common bile duct is 15 mm or greater, obstruction or choledocholithiasis is possible. Narrowing of the distal common bile duct with a normal or dilated proximal duct is characteristic of pancreatic edema and fibrosis, and a long, tapered narrowing suggests pancreatitis. Opacification of the biliary tree depends on the functioning hepatocyte, and the predicted rate for successful visualization of the common duct with a bilirubin level of 1 mg/100 ml or less is about 92.5%; only 9.3% of patients with a level of 4 mg/100 ml or more show the common duct.

8635 ULTRASONIC CHOLANGIOGRAPHY. GRAY-SCALE B-SCAN EVALUATION OF THE COMMON BILE DUCT.

(Eng.) Goldberg, B. B. (Episcopal Hosp., Philadelphia, PA 19125). *Radiology* 118(2):401-404; 1976.

Twelve patients with jaundice were examined using gray-scale B-scanning to evaluate biliary duct dilatation, as well as possible choledocholithiasis. In an additional case, a definitive experiment was performed to establish the exact extent of the ability of ultrasound to localize the common bile duct and tributaries, as well as to detect choledocholithiasis. The patient, a 58-yr-old man who had undergone cholecystectomy 5 yr previously, presented with jaundice. No mass was detected using ultrasound or roentgenography. Gray-scale B-scan ultrasonograms revealed dilatation of the common bile duct and portions of the hepatic ducts; strong reflecting interfaces were seen arising from within the common duct, consistent with the diagnosis of choledocholithiasis. Transhepatic cholangiography confirmed the ultrasonic findings. When the ultrasonic examination was repeated, there was evidence of persistent dilatation of the common bile duct; there was no evidence of the strong echoes produced by the stones. A T-tube cholangiogram confirmed the duct dilatation and the absence of stones. Water-soluble contrast material containing microscopic air bubbles was injected through a T-tube into the common duct. Multiple internal echoes were recorded from within the previously echo-free bile-filled duct, due to the air bubbles. For further confirmation that the common bile duct was being detected ultrasonically, large air bubbles were injected and obliterated a significant portion of the distal wall of the duct. Strong echoes were produced along the anterior surface, which was expected, since air reflects almost all of the ultrasonic beam. Of the 12 patients studied, 7 had no evidence of a dilated bile duct, and the diagnosi was intrahepatic jaundice. All five cases of ultrasonically demonstrated dilated bile ducts were confirmed at surgery or autopsy. In one case, stone were identified ultrasonically in both the gallbladder and distal common bile duct. The results suggest that cholangiosonography should be the initial procedure of choice when differentiation between hepatocellular jaundice and posthepatic obstruction is important.

8636 SEGMENTAL ULTRASONIC TEST FOR THE STUDY OF CHOLECYSTODYSKINESIA.

(Eng.) Schennetten, F.; Pomaska, J. (35 Schluterstrasse, 1 Berli 12, Charlottenburg, E. Germany). *Ultrasonics* 13(6): 279-281; 1975.

The effect of ultrasonic stimulation, applied to four different points, on the gallbladder was studied in 10 women (aged 35-61 yr) with vague symptoms in the right upper quadrant. The patients received an i.v. injection of 20 ml of 40% biligrafin [the disodium salt of adipic acid (3-carboxy-24, 6 triodoaniline)]. X-rays of the gallbladder area were taken before and at intervals after the injection. This was followed by ultrasonic stimulation (applied using the impulse technique) for 10-20 min at frequencies of 3 megaHZ, and an effective intensity of 1.4-2.8 W/cm^2, with paraffin oil as a contact agent. The dorsal segments (a strip across the tip of the right scapula and a paravertebral str about a handsbreadth from the midline and extending upward from the 12th rib) were subjected to ultrasonic stimulation of a weaker intensity but longer duration than the ventral segment. The gallbladder shadow was analyzed planimetrically, and an approximate volumetric calculation was attempted. The gallbladder responded to segmental ultrasonic stimulation by both contraction and dilatation, presumably through a cutaneous visceral reflex arc; this response was qualitatively and quantitatively different from that obtained after an egg yolk meal Segmental ultrasonic stimulation of the gallbladder seems to be a suitable complement to fatty meal treatment. In addition, it offers the possibility of differentiating between the hyperkinetics and hypokinetic forms of gallbladder dyskinesia. Finally, it was observed that a more marked effect on the gallbladder can be produced by dorsal-segmental stimulation than by stimulation over the ventral points.

8637 CHOLECYSTOKINETIC CHOLECYSTOGRAPHY: EFFICACY AND TOLERANCE STUDY OF SINCALIDE.

(Eng.) Sargent, E. N.; Meyers, H. I.; Hubsher, J. (Univ. Southern California Medical Center, 1200

State St., Los Angeles, CA 90033). *Am. J. Roent-*
nol. 127(2):267-271; 1976.

cause contraction of the gallbladder in conjunc-
on with cholecystography may permit an additional
sessment of gallbladder function, the ability of
ncalide (the C-terminal octapeptide fragment of
olecystokinin) to cause gallbladder contraction
s studied in 40 patients undergoing cholecysto-
aphy. On the day prior to the examination, the
tients received a fatty meal for lunch and a fat-
ee evening meal. Sodium ipodate (3 g) was admin-
tered p.o. 12 hr prior to the examination. Within
15 min of an i.v. injection of sincalide (20 ng/
), maximum gallbladder contraction (i.e., a 40%
duction of the gallbladder area on at least 1
diograph) occurred in 24 patients. The remaining
patients required a second dose of 20 ng/kg
ncalide to achieve maximum gallbladder contrac-
on. The total dose administered to each patient
nged from 1.0 to 7.8 μg (average, 2.5 μg). The av-
age reduction in gallbladder size was 52% of the
einjection area (range, 5.5-100%). Six patients
owed complete gallbladder emptying. Cystic duct
sualization occurred in 31 patients, and common
le duct visualization occurred in 35. Transient
ld abdominal pain, cramps, or nausea occurred in
% of the patients. The administration of sincalide
oduces a peak gallbladder contraction earlier than
es a fatty meal. Cholecystokinetic cholecysto-
aphy may prove to be helpful in the diagnosis
acalculous cholecystitis if a relation can be
tablished between gallbladder contractility and
olecystitis. It may also be helpful in visualiz-
g small gallstones, which cannot be seen without
llbladder contraction.

38 CARCINOEMBRYONIC ANTIGEN-LIKE SUBSTANCES
OF HUMAN BILE. ISOLATION AND PARTIAL
ARACTERIZATION. (Eng.) Svenberg, T. (Danderyd
sp., Danderyd, Sweden). *Int. J. Cancer* 17(5):588-
6; 1976.

ree different types of biliary carcinoembryonic
tigen-like material were isolated and partially
aracterized to increase the cancer specificity of
e carcinoembryonic antigen (CEA) assay. Hepatic
le was obtained from the T-tube drains of anicteric
tients operated on for gallstones of the common
le duct. Gallbladder bile was obtained from pa-
ents with gallstones by puncture of the gallbladder
the beginning of cholecystectomy. In all, 5
mples of normal gallbladder bile, 35 samples of
patic bile, 10 samples of white bile (bile sub-
cted to inflammation), and 10 samples of bile
om gallbladders with stones but without obstruc-
on were examined. The presence of CEA and/or CEA-
ke material in bile was determined by rocket-line
munoelectrophoresis using antitumor extract and
ference CEA. These studies identified three
ecies of CEA-like macromolecules, called biliary
ycoprotein (BGP) I, II, and III, in human bile.
P I was in normal gallbladder bile and hepatic
le, but not in white bile, and was immunologically
lated to CEA and NGP (the normal CEA-like glyco-
otein). BGP I differed immunologically from CEA
in that it lacked the tumor-associated determinants of CEA. It was different from NGP and CEA in that it contained BGP I-specific determinants, as revealed by anti-BGP I antibodies. In bile from gallbladders with an obstructed outlet and subjected to cholecystitis, a nonmalignant inflammatory process, BGP I was replaced by BGP II and III. Immunologically and physicochemically, BGP II and III appeared closely similar to NGP and CEA, resp. Until the chemical structure of CEA and of noncancer-related CEA-like substances has been fully established, the theoretical implications of materials like BGP I, II, and III in the field of CEA research cannot be understood completely.

8639 AN IMMUNOPEROXIDASE TECHNIC FOR THE DEMONSTRATION OF THE HEPATITIS B SURFACE ANTIGEN IN HUMAN LIVERS. (Eng.) Afroudakis, A. P.; Liew, C.-T.; Peters, R. L. (John Wesley Hosp., 2825 South Hope St., Los Angeles, CA 90007). *Am. J. Clin. Pathol.* 65(4):533-539; 1976.

A sensitive method for demonstrating the site of hepatitis B surface antigen (HBsAg) in fixed human liver tissue embedded in either paraffin or araldite is described. The method uses the peroxidase-rabbit antiperoxidase linkage through goat anti-rabbit to rabbit anti-HBsAg. Six counterelectrophoresis slides utilizing agarose were made using two different HBsAg titers electrophoresed against antisera from human sources. HBsAg-HBs antibody (HBsAb) complexes on unfixed agar slides were stained positively by orcein but not by peroxidase. Positive stain was obtained with the immunoperoxidase technique only on fixed (with B-5, formalin, or Bovin's fixative) and unfixed agar slides where the bound HBsAb had been removed previously from the precipitating arcs by exposure to the proteolytic activity of a 0.1% solution pronase. None of the fixatives affected the intensity of the reaction. Specimens of human liver tissue were fixed in either B-5 or formalin and embedded in araldite. A brown cytoplasmic stain of variable intensity developed that was proportional to the amount of antigenic material in the liver cells. The stained cytoplasm corresponded in shape and distribution to the eosinophilic, finely granular, ground glass-appearing cytoplasm. This method allows confirmation of positive reaction by appropriate blocking controls and is more sensitive than the orcein stain of Shikata, but slightly more time-consuming.

8640 RADIOSELENIUM IN DUODENAL ASPIRATE AFTER SECRETIN AND PANCREOZYMIN STIMULATION. A RELIABLE TEST OF EXOCRINE PANCREATIC FUNCTION. (Eng.) Scuro, L. A.; Dobrilla, G.; Vantini, I.; Franchi, R.; Marabini, A.; Angelini, G.; Cavallini, G.; Vaona, B.; Castegnaro, A. (Istituto di Clinica Medica III, dell'Universita di Padova, Policlinico Borgo Roma, 37100 Verona, Italy). *Rend. Gastroenterol.* 7(3):177-184; 1975.

A method for testing pancreatic exocrine function based on the determination of radioactivity in the duodenal contents after stimulation with secretin and pancreozymin was evaluated in 10 patients with chronic relapsing pancreatitis and 10 normal subjects following the i.v. injection of ^{75}Se-selenomethionine (4 μCi/kg). GIH secretin (1 clinical U/kg) and cholecystokinin (1 Ivy U/kg) were administered i.v. 30 min after selenomethionine, and duodenal contents were collected in six consecutive 30-min samples. The mean volume of the duodenal aspirate from the patients was significantly lower than that from controls in all but the last time period. Bicarbonate content and pancreatic enzyme content were similarly decreased in the aspirate from the patients. The radioactivity of the aspirates was similar to that of the controls prior to stimulation, but after hormonal stimulation, the mean radioactivity of control aspirates was significantly higher than that of patient aspirates. While there was some overlap in the third and fourth collection periods, when the pooled samples of all collection periods were compared, no overlap was found. The correlation coefficients between each enzymatic activity and the percent of radioactivity in the duodenal aspirates ranged from 0.6 to 0.9 in the patients, the highest value being 0.9 for chymotrypsin. The mean correlation coefficient in the control aspirates was 0.25. Gastric radioactivity measured in the same subjects was initially not appreciable and became a little more than 50% of the duodenal aspirate activity only in the 60- to 120-min period. The percentage of radioactivity in precipitated gastric protein never exceeded 20%. Less than 1% of radioactivity was found in the bile in two patients with T-tubes in the common duct. The specificity and accuracy of the test are emphasized.

8641 UPPER-GASTROINTESTINAL ENDOSCOPY IN PERSPECTIVE. (Eng.) Salter, R. H. (Cumberland Infirmary, Carlisle, CA2 7HY, England). *Lancet* 2(7940):863-865; 1975.

GASTROINTESTINAL DISEASES

ESOPHAGUS

9 FUNCTIONAL EVALUATION OF THE INTERPOSED COLON AS AN ESOPHAGEAL SUBSTITUTE. (Eng.) rk, J.; Moraldi, A.; Moossa, A. R.; Hall, A. W.; eester, T. R.; Skinner, D. B. (Pritzker Sch. icine, Univ. Chicago, 950 East 59th Street, Chio, IL 60637). *Ann. Surg.* 183(2):93-100; 1976.

examine the motility pattern of esophageal repement and the mechanisms of prevention of reflux regurgitation, manometric, fluoroscopic, and lux tests were carried out in five Rhesus monkeys four human adults with colonic reconstruction the esophagus. Esophageal resections had been formed for advanced achalasia and stricture in patients, peptic stricture in one, and esophageal coma in the fourth. Gravity was the principal ce responsible for transit of material through graft. Spontaneous propulsive activity was ficult to quantify. Haustral, multihaustral, and uential haustral contractions occurred, and the ements were completed more slowly than esophageal istalsis. Intermittent straining and coughing both monkeys and humans caused contrast material flow out of the colon segment in both directions. the monkeys, 71% of stimuli (0.1 normal concentran HCl, hot coffee, whiskey, carbonated beverage, bisacodyl) produced a response in the colon segt. Among the human patients, stimulation with normal concentration HCl, carbonated drink, or ffee produced a sequential multihaustral contracn in 8 and segmental or synchronous contraction 16 of 41 tests. Reflux could be controlled kly and variably at the diaphragmatic hiatus and esophagocolic anastomosis and was readily overe by increased intraluminal pressure and distenn. Washing back and forth was observed with piration in the monkeys when barium distended the logastric cavity. Esophageal peristalsis was uired to return refluxed material. The final rier to regurgitation is the cricopharyngeal scle.

30 COMPLICATIONS ASSOCIATED WITH ESOPHAGOGASTRODUODENOSCOPY AND WITH ESOPHAGEAL ATION. (Eng.) Mandelstam, P.; Sugawa, C.; Sil-, S. E.; Nebel, O. T.; Rogers, B. H. G. (Dept. licine, Univ. Kentucky, Lexington, KY 40506). *strointest. Endosc.* 23(1):16-19; 1976.

complications arising from esophagogastroduooscopy and of esophageal dilatation were analyzed a series of 211,410 p.o. endoscopic examinations. overall rate of complications due to esophagostroduodenoscopy was 507/211,410 (1.32/1,000 aminations). The major complications included rforation (70 cases, 5 fatalities), bleeding (63 ses, 2 fatalities), cardiopulmonary (129 cases, fatalities), and infection (17 cases, 0 fatalities). sites of perforation included the pharynx and per esophagus (14 cases), mid and distal esophagus 2 cases), stomach (10 cases), duodenum (2 cases), d afferent loop (1 case). The sites of bleeding cluded the esophagus (8 cases), stomach (19 cases), duodenum (2 cases), and afferent loop (1 case). Initial or recurrent esophageal variceal bleeding was apparently provoked by endoscopy in four patients. Most of the cases of postendoscopy bleeding from the stomach followed biopsy. The cardiopulmonary complications included aspiration (25 cases), respiratory arrest secondary to i.v. diazepam (23 cases) or topical pharyngeal anesthesia (3 cases), myocardial infarction (6 cases), and cardiac arrest or ventricular fibrillation (8 cases). The overall complication rate for esophageal dilatation using mercury bougies was 4.25/1,000; that for dilatation using metal olives was 6.1/1,000; and that for pneumatic or mechanical dilatation was 18.4/1,000. These complications included perforation (12/13,139 dilatations in which mercury bougies were used; 33/9,431 with metal olives; and 14/1,224 with pneumatic or mechanical dilatation), bleeding (45, 8, and 4 dilatations with the respective techniques), cardiopulmonary complications (1, 5, and 1, resp.), and infections (0, 2, and 0, resp.). The results confirm the prevailing safety of p.o. endoscopy and dilatation, but indicate thay any suspicion of perforation requires prompt radiologic investigation and that cardiopulmonary resuscitation should be immediately available in the endoscopy room.

8681 ALKALINE REFLUX ESOPHAGITIS AFTER TOTAL GASTRECTOMY. (Eng.) Morrow, D.; Passaro, E. R., Jr. (U.C.L.A. Sch. Medicine, Los Angeles, CA). *Am. J. Surg.* 132(2):287-291; 1976.

The cases of five patients with severe alkaline reflux esophagitis after end-to-side esophagojejunostomy with distal enteroenterostomy (loop EJEE) in whom significant symptomatic improvement occurred after revision to a Roux-en-Y esophagojejunostomy with a jejunal pouch (Roux-en-Y EJ) are presented. The clinical course of seven other patients who underwent one of these procedures following total gastrectomy is reviewed. All patients underwent total gastrectomy for the treatment of the Zollinger-Ellison syndrome. All five patients with initial loop EJEE had incapacitating alkaline reflux esophagitis, which was manifested in one patient primarily by a bitter brash, in another by bitter brash and recurrent vomiting, in two by retrosternal burning pain, and in the remaining patient by severe retrosternal pain, vomiting, and bitter brash. After conversion, symptoms of reflux esophagitis abated. Four patients had mild to severe dumping prior to the conversion. Four patients lost 25, 45, 70, and 75 pounds, resp., after the initial operation; after the reconstruction, these patients regained 10-35 pounds. In the second group of seven patients, five had Roux-en-Y EJ and two had loop EJEE reconstruction. Two of the five patients with Roux-en-Y reconstruction had mild to moderate retrosternal pain, and three had no pain; all denied vomiting, regurgitation or bitter brash, diarrhea, or dumping. One of the two patients with loop EJEE had severe alkaline reflux esophagitis, moderate dumping, and weight loss, while the other was asymptomatic.

These results suggest that Roux-en-Y EJ is an excellent reconstructive procedure following total gastrectomy for Zollinger-Ellison syndrome, and that loop EJEE may not be the optimal procedure because of esophagitis and dumping.

8682 ALTERATION IN ESOPHAGEAL MOTILITY AFTER LARYNGECTOMY. (Eng.) Duranceau, A.; Jamieson, G.; Hurwitz, A. L.; Jones, R. S.; Postlethwait, R. W. (Dept. Surgery, Hotel Dieu De Montreal, 3840 Rue St. Urbain, Montreal, Quebec H2W 1T8 Canada). *Am. J. Surg.* 131(1):30-35; 1976.

Manometric studies were conducted among 10 patients who had undergone laryngectomy for carcinoma of the larynx to determine the status of esophageal motility. Six patients without esophageal disease served as controls. The resting pressure of the upper esophageal sphincter (UES) in the control group was 34.3 mm Hg, and the peak postdeglutition pressure was 46.4 mm Hg. Corresponding values for the laryngectomized patients were 12.9 and 24.5 mm Hg, resp. The UES coordination with the pharynx was normal in 98.9%, and relaxation was complete in 97% of swallows in the control group, compared to 73.9% and 65.3%, resp., in the test group. In the proximal esophagus in controls, the wave pressure had a mean peak of 24.1 mm Hg, and peristalsis was normal in 99% of waves. The patients with laryngectomy had a mean peak pressure of 13.7 mm Hg, and only 76% of the waves showed a normal peristaltic pattern. In the distal esophagus, controls had a mean peak pressure of 58.7 mm Hg, compared to 20.4 mm Hg in the test group. All waves in the control group were normal, but only 85% of waves of laryngectomized patients were normal. No significant differences between controls and laryngectomees were noted in the resting and postdeglutition lower esophageal sphincter (LES) pressures or in the degree of LES coordination and relaxation. It is suggested that disturbances in esophageal motility may be relatively frequent after laryngectomy.

8683 INFLUENCING THE LOWER ESOPHAGEAL SPHINCTER BY PHENYLALANINE-LYSINE-VASOPRESSIN. POSSIBLE EFFECTS ON BLEEDING ESOPHAGEAL VARICES. (Ger.) Wienbeck, M.; Bovelet, M.; Hausamen, T.-U.; Strohmeyer, G. (Medizinische Einrichtungen der Universitat, II. Medizinische Klinik u. Poliklinik, Moorenstr. 5, D-4000 Dusseldorf 1, W. Germany). *Z. Gastroenterol.* 14(3):333-341; 1976.

The effect of pressor agents on lower esophageal sphincter (LES) pressure and gastroesophageal reflux and its clarification by serum gastrin level were examined in 24 adult volunteers without esophageal pathology. LES pressure was determined by the continuous withdrawal method. 2,3-Phenylalanine-8-lysine-vasopressin (PLV) was infused at the following doses: 0.54, 1.08, 2.7, 10, 27, and 54 mU/kg/hr each, for 28 min. LES pressure tended to increase if the initial PLV doses were below 2.7 mU/kg and then to reverse direction, falling below initial levels, if the PLV doses were increased above 2.7 mU. Only the 0.54-mU dose was significant ($p<0.05$). High PLV doses elicited a direct and significant fall ($p<0.05$) in LES pressure, which then remained level during the test period. At 2.7 mU, PLV elevated the resting LES pressure from 12.3 to 17.9 mm Hg. PLV had no effect on serum gastrin levels; resting LES pressure and serum gastrin coulc not be correlated. The probands became increasingl more pallid as the infusion continued at 2.7 mU PLV. Convulsive abdominal pain was reported at 10 mU. Peripheral blood pressure in most probands remained unchanged; in no case was there a hypertensive episode or cardiac symptoms. A continuous, long-term infusion of lower doses of pressor substances is recommended for the treatment of esophageal reflux.

8684 ESOPHAGEAL FUNCTION AFTER FUNDOPLICATION (NISSEN'S METHOD). (Ger.) Krejs, G. J.; Buhler, H.; Akovbiantz, A.; Keller, H.; Landolt, M.; Blum, A. L. (Medizinische Klinik, Stadtspital Triemli, CH-8063 Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 106(24):825-828; 1976.

STOMACH

692 GASTROINTESTINAL BLEEDING DUE TO ASPIRIN. ADVANTAGES OF LYSINE ACETYLSALICYLATE.
Fre.) Aron, E.; Delbarre, B.; Besnard, J.-C.
Clinique Medicale A, Faculte de Medecine, 37032
ours Cedex, France). *Therapie* 31(2):247-256; 1976.

he results of a comparative study of aspirin-induced
astrointestinal hemorrhage in humans and rats are
resented. Aspirin (ASP) and lysine acetylsalicy-
ate (LAS), at 350-mg/kg doses, p.o., induced an
verage 48-hr blood loss in rats of 1,054 µl ($p<0.01$)
nd 250 ($p>0.05$) µl, resp., compared to 136 µl in
um arabic controls. Fecal loss of ^{51}Cr-labeled
BC was 142 and 192 µl, resp., after LAS i.v. injec-
ions equivalent to 100 and 200 mg/kg ASP; since
ontrol values averaged 239 µl, both LAS losses are
ot significant ($p>0.05$). An increase in fecal RBC
oss from 87 to 98 µl ($p>0.05$) was established by
AS, i.m., at doses equivalent to 100 mg/kg ASP.
n man, 4 g ASP, p.o., did not significantly alter
lood loss; there was also no difference before,
uring, or after administration of 2 g ASP, i.v. or
.m. In solubility studies, 200, 300, and 400 mg/
g ASP induced a salicylemia of 22, 40, and 52 µg/
l, but the same doses of LAS elicited increases of
1, 112, and 148 µg/ml. Similar results were
btained in 28 subjects, with gastrointestinal
isease. In another study in 20 subjects, the LAS
bsorption rate was three times that of ASP at 10
in postingestion. In general, microscopic hemor-
hage after LAS is 10% compared to 70% after ASP.

693 ROENTGEN FEATURES OF THE SUPERFICIAL DEPRESSED TYPE OF EARLY GASTRIC CARCINOMA.
Eng.) Koga, M.; Nakata, H.; Kiyonari, H.; Inakura,
.; Tanaka, M. (Dept. Radiology, Natl. Cancer Center
osp., Kyushu, Japan). *Radiology* 115(2):289-292;
975.

he essential roentgen findings and radiographic
echnique used in the diagnosis of early gastric
arcinoma are described. Coliopan (one ampule,
.m.) is given 5 min before examination to make the
tomach hypertonic, suppress gastric secretion, and
elay the passage of barium into the small bowel.
double-contrast study is then performed for
etailed examination of any superficial depressed
gastric carcinoma. Barium is given in 100-ml increments, for a total of about 300 ml. Air (200-300 ml) is then introduced via a small nasogastric tube. The patient is generally supine, although for studies of the posterior wall of the upper portion of the body and fundus, the Schatzki position is recommended. For lesions of anterior stomach wall, the barium dosage is usually 30-50 ml and the patient is prone; as much as 500 ml of air may be introduced. With respect to roentgen findings, at the stage when diagnosis is possible, the gross appearance of gastric carcinoma is that of an excavation, often associated with a deeper central ulceration. The most important feature of the excavation is its irregular outline, consisting of zigzag lines conforming to the areae gastricae. The excavation is shallow and its base may be granular or uneven. The area surrounding the excavation usually contains converging mucosal folds that are abruptly narrowed or terminated at the tips and often show clubbing. An asymmetric elevated area partially surrounding the excavation may be an indication of carcinoma.

8694 MENETRIER'S DISEASE: SERIAL MORPHOLOGICAL SECRETORY, AND SEROLOGICAL OBSERVATIONS.
(Eng.) Berenson, M. M.; Sannella, J.; Freston, J. W. (Univ. Utah Medical Center, 50 North Medical Drive, Salt Lake City, UT 84132). *Gastroenterology* 70(2):257-263; 1976.

A case of Menetrier's disease in a 51-yr-old man is presented. His initial complaints were malaise, nausea, and vomiting. An upper gastrointestinal series revealed hypertrophic gastric folds; the patient had hypoproteinemia, low gastric acid secretion, and several gallstones. He did not respond to cholecystectomy and subsequently developed pedal edema. The diagnosis was made from a full thickness gastric biopsy taken at laparotomy. Depressed serum immunoglobulins, elevated plasma gastrin levels, and an elevated bowel protein loss were also observed. Antibodies to parietal cells and to various dietary substances were detected. Over the next 12-18 months, the gross abnormalities in the stomach gradually normalized, as determined by gastrointestinal radiography, endoscopic appearance, and gastric peroral biopsies. The histological picture during this period changed from hypertrophy of the gastric mucosa to atrophic gastritis. Functionally, there was also a normalization of gastric acid secretion, serum gastrin levels, serum protein content, and gastrointestinal loss of protein after atropine administration. The serum antibodies to parietal cells and foodstuffs disappeared.

8695 PROSPECTIVE STUDIES OF GASTRIC SECRETION IN TRAUMA PATIENTS. (Eng.)

Stremple, J. F. (Veterans Admin. Hosp., University Drive C, Pittsburgh, PA 15240). *Am. J. Surg.* 131(1):78-85; 1976.

Gastric secretion studies in 36 trauma patients are reported. There were 16 cases of intra-abdominal injury, 15 of cranial trauma, 4 with chest injuries, 3 with extensive burns, 2 multiple extremity injury, and 2 with spinal cord injuries. Sixteen patients were categorized as having more severe injuries. Gastric acid secretion in more severely injured patients increased sharply between 24 and 36 hr after trauma and continued to rise until 72 hr. Patients with less severe injuries had a smaller increase in gastric acid secretion, to a peak at 36 hr, followed by marked diminution to near zero at 72 hr. Patients with abdominal injuries had a marked increase in gastric acid secretion between 24 and 36 hr, while patients with cranial injuries did not have increased gastric acid secretion. Severely injured patients had a marked increase in pepsin output between 24 and 36 hr, while pepsin output decreased throughout the 72 hr period in less severely injured patients. Patients with abdominal injuries had a marked increase in pepsin output between 24 and 36 hr, while patients with cranial injuries had an almost continuous decrease in pepsin output. Serum gastrin levels were never elevated, and there was no correlation between them and the severity or site of injury. Gastric mucosal cell renewal, as estimated by gastric juice DNA, was increased in patients with severe injury, and except for a valley at 48 hr, this increase was steady throughout the 72-hr period. Less severely injured patients had markedly increased gastric juice DNA at 36 hr, a slight reduction at 48 and 60 hr, and another increase at 72 hr. Patients with abdominal injuries had decreased gastric juice DNA after 24 hr, while in those with cranial injuries, this parameter reached a peak at 36 hr. Urinary nitrogen excretion increased in several and less severely injured patients to a maximum at 36 hr after trauma, followed by a decline. Patients with cranial injury had initially normal urinary nitrogen levels, which reached a peak at 24 hr, and then declined. Patients with abdominal injury had markedly elevated urinary nitrogen at 24 hr. Gastric juice protein output at 72 hr was two to three times greater in patients with more severe and abdominal injuries than in patients with less severe and cranial injury. Sodium and urea concentrations paralleled protein content, suggesting increased permeability. 17-Hydroxycorticosteroid excretion increased only after 24 hr in patients having more severe injuries and those with abdominal injuries, while it was increased earlier in patients with less severe and cranial injuries. Similar patterns existed for 17-ketogenic steroid and 17-ketosteroid. There were no significant changes in blood gases or in coagulation factor regardless of site or severity of injury. It is concluded that the gastric mucosa must be protected by gastric antacids and/or gastric aspiration before 24 hr after trauma and continued through at least 72 hr.

8696 TESTING OF A NEW ANTACID WITH THE HEIDELBERGER CAPSULE IN HEALTHY PERSONS. (Ger.)

Aenishanslin, H. W.; Stalder, G. A. (Medizinische Universitats-Poliklinik, Hebelstrasse 1, 4056 Basel, Switzerland). *Praxis* 64(26):843-847; 1975.

Experiences with a new antacid, Andursil®, in 20 healthy volunteers with a Heidelberger capsule are reported. Each 5 ml of the antacid contains 200 mg aluminum hydroxide and 200 mg magnesium hydroxide in suspension, 200 mg aluminum hydroxide-magnesium carbonate as a co-dried gel, and 150 mg dimethylpolysiloxane. Its effect was compared with a commercial preparation (Alucol®) by radioprobes after maximal pentagastrin stimulation. Each subject received one dose of Andursil and Alucol on two different days at intervals of 2-10 days. The maximum pH increase was higher for Andursil in 8 of 18, lower in 1 of 18, an the same in 9 of 18; 2 cases failed to respond. Alkali time was longer for Andursil in 5 of 18, shorter in 3 of 18, and the same in 10 of 18. Only the higher pH increase was significantly different, confirming Andursil as the more potent acid buffer.

8697 BASAL AND MEAT EXTRACT PLASMA GASTRIN BEF AND AFTER PARIETAL CELL VAGOTOMY AND SELEC IVE GASTRIC VAGOTOMY WITH DRAINAGE IN PATIENTS WITH DUODENAL ULCER. (Eng.)

Fischer, J. E.; Kragelund, E.; Nielson, A.; Wesdorp, R. I. C. (Harvard Medical Sch., Boston, MA). *Ann. Surg.* 183(2):167-173; 1976

Plasma gastrin (PG) and gastric acid secretion in response to various stimuli were determined before and 2-3 months after surgery in 43 patients with duodenal ulcer. In 32 patients in whom no pyloric stenosis was found, parietal cell vagotomy (PCV) was performed, while 11 patients with varying degre of pyloric stenosis underwent selective vagotomy an pyloroplasty (SV + P). Preoperatively, both groups had comparable mean basal PG values (52 pg/ml in th PCV group and 51 in the SV + P group). After stimu ation with meat extract, the mean PG level of the total group rose to 173 pg/ml at 30 min and was 56 pg/ml by 90 min. Postoperatively, the mean basal PG level increased significantly in both groups (107 pg/ml in the PCV group, $p<0.02$; 152 in the SV + P group, $p<0.05$). After stimulation with meat extract, the mean PG in the PCV group was 260 pg/ml at 30 min and 117 pg/ml at 90 min, while in the SV + P group, the PG was 300 pg/ml at 30 min and 126 pg/ml at 90 min. The gastrin response to meat extract was not significantly different between the two groups. Postoperatively, the acid secretion respon to all stimuli was reduced. Basal acid secretion in the PCV group was only 0.9 mEq/hr. This rose to 3.6 mEq/hr after meat extract stimulation and to

.8 mEq/hr after pentapeptide stimulation. Insulin-
imulated secretion was reduced 92% (2.5 mEq/hr).
the SV + P group, the basal acid secretion was
7 mEq/hr. Following insulin stimulation, only 1.1
q/hr was secreted, and following meat extract stim-
ation the value was 1.3 mEq/hr. There was no
gnificant difference in basal and meat extract
imulated PG levels between insulin-negative and
sulin-positive patients in both treatment groups.
ter PCV, there was a positive relation (correl-
ion coefficient=0.62) between meat extract-stimu-
ted PG levels and gastric acid response with a slope
gnificantly different from zero (p=0.05).

STOMACH

Peptic Ulcers

8728 A COMPUTERIZED QUESTIONNAIRE ANALYSIS OF DUODENAL ULCER SYMPTOMS. (Eng.) Earlam, R. (London Hosp., Whitechapel, London, E1 1BB, England). *Gastroenterology* 71(2):314-317; 1976.

The characteristics, daily routine, and symptoms of 100 duodenal ulcer patients were compared with those of 100 controls to analyze the life styles of patients and controls. There were no significant differences between the patients and controls in age, weight, height, lean body mass, surface area, nationality, religion, marital status, tobacco or alcohol consumption, occupation, or in the amount of night work, shift work, or overtime

e. All ulcer patients had suffered from abdominal
n due to indigestion during the daytime. Thirty-
had bled from the intestinal tract, and 11 had
forated ulcers. Sixteen had an ulcer history of
r or less, and 35 had an ulcer history of longer
n 15 yr. Forty-six patients had one or more
atives with ulcers, compared with eight in the
trol group. Fifty-seven patients had attacks of
n lasting less than 4 weeks, and the same propor-
n had relief for a similar period. Seventy-four
ients said that the pain was worse with worry,
64 thought that it was unchanged during vaca-
ns. In 24, indigestion was worse in winter, but
thought that there was no seasonal variation.
nty-three patients had pain immediately before
eal, 16 had pain 0-1/2 hr following the meal,
had pain 30 min-1 hr following the meal, and 13
pain 1-2 hr following the meal. The pain made
patients eat less and 19 eat more. The mean
ght of those with ulcers (67 kg) was significant-
less than that of controls (72 kg) at the 1%
el, but not at 0.5%. Eighty ulcer patients said
indigestion was helped if fried foods were
ided, and 64 avoided particular foods, including
try, cucumbers, curry, and onions. Heartburn
urred in 59 patients. Regurgitation of gastric
tents into the mouth occurred in 64 patients and
associated with heartburn in 29. Eighty-eight
ients were awakened at night by indigestion, while
e of the controls were awakened for this reason.
nty-seven patients had nocturnal pain lasting
en or more consecutive nights, 24 had pain three
four times a week, 21 had pain one or two nights
eek, and 16 had pain one night a month or less.
evidence suggests that there are several clinic-
characteristics of duodenal ulceration, independ-
of the daily routine of life, which might be
ful in measuring the severity of the disease
cess.

9 NATURAL HISTORY AND MORPHOLOGY OF SECRETA-GOGUE-INDUCED DUODENAL ULCERS IN RATS.

g.) Gaskin, R. J.; Gad, A.; Barros D'Sa, A. A.
Joffe, S. N.; Baron, J. H. (Dept. Surgery, Royal
tgraduate Medical Sch., Hammersmith Hosp., London
2 OHS, England). *Gastroenterology* 69(4):903-
; 1975.

animal-model duodenal ulcer comparable with the
an disease was prepared, and the time course of
ntaneous healing of these ulcers was studied.
phologically typical ulcers were produced in the
st part of the duodenum in 300 male Wistar rats
a 24-hr s.c. infusion of pentagastrin (4 μg/kg/
) and carbachol (0.8 μg/kg/min). Groups of ani-
s were killed daily for 14 days, and their stom-
s and duodenums were removed, opened, and exam-
d macroscopically and microscopically. The
ions were graded on a seven-point scale of in-
asing severity according to the gross character-
ics: 0, normal; 1, inflammation; 2, petechiae;
erosions; 4, definite ulcer crater; 5, penetra-
g ulcer; and 6, perforated ulcer. All 67 animals
mined at the end of the 24-hr infusion developed
or more definite ulcers (grades 4-6) in the
st part of the duodenum. In one-third of the rats, the second and third parts were involved as well, and gastric ulcers were found in two animals. Of the 300 rats studied, 34% died with grade 6 ulcers within 48 hr. Ulcer healing began on the first postinfusion day, when 3 of the 46 rats studied had only grade 3 lesions. After the fifth day, the few remaining grades 5 and 6 lesions were those that had perforated and sealed spontaneously. Healing was essentially complete, with no macroscopic ulcers, by the end of 14 days. The acute lesions produced were macroscopically and microscopically comparable to the acute duodenal ulcers seen in man, and some of the persistent ulcers, such as those that had perforated and sealed spontaneously, were in many ways similar to chronic duodenal ulcers in man. This model may prove to be a valid system for testing the efficacy of various medical or surgical regimens for healing duodenal ulcers.

8730 EXPERIMENTAL CHRONIC GASTRIC ULCER DUE TO ISCHEMIA IN RATS.

(Eng.) Guth, P. H.; Paulsen, G.; Foroozan, P. (691/111C, Veterans Admin. Wadsworth Hosp., Los Angeles, CA 90073). *Am. J. Dig. Dis.* 20(9):824-834; 1975.

The gross and histologic sequences of tissue injury and repair were studied following the induction of chronic gastric ulcers in male Wistar rats by ischemia. The left and right gastroepiploid arteries and veins of fasted, anesthetized rats were ligated; control rats were sham-ligated. The animals were sacrificed at intervals between 1 hr and 12 months postoperatively, and the lesions and stomach were examined. Lesions developed in all ligated rats, solely in the corpus of the stomach. Small hemorrhagic areas appeared in half the animals within 1 hr of ligation, in three-fourths of the animals within 4 hr, and in all the animals within 8 hr. At 8 hr, the erosions were often linear, and free blood was present in the lumen of the stomach; by 2 days, there were large corpus hemorrhagic erosions; at 3-5 days, there were single, large ulcers involving nearly the entire corpus. In the ulcerated area, the mucosa and muscularis mucosae were destroyed, thick granulation tissue filled the submucosa, and the muscularis propria was severely damaged. Progressive healing occurred after the fifth day, and 75% of the ulcers showed complete gross healing in 2-8 weeks. Histologically, healing and mucosal regeneration occurred by the outgrowth of a layer of cells from the adjacent intact epithelium extending over the surface of the ulcer. Invaginations from this covering layer of cells formed a glandular mucosa composed of mucous cells. Later, parietal and chief cells appeared, and eventually (after about 6 months) a normal corpus-type mucosa covered the entire corpus. With time, smooth-muscle fibers appeared in the outer half of the dense submucosal granulation tissue and, within 6-12 months, a normal muscularis mucosae, submucosa, and muscularis propria were present. These studies show that ischemia can give rise to chronic gastric ulcers, and that all elements of the gastric wall, including the mucosa, muscularis mucosae, and the muscularis propria, can regenerate fully.

8731 PEPTIC ULCER IN CHILDREN WITH GASTRIC TUBE INTER-POSITION.

(Eng.) Anderson, K. D.; Randolph, J. G.; Lilly, J. R. (Children's Hosp. Natl. Medical Center, 2125 13th St., N.W., Washington, DC 20009). *J. Pediatr. Surg.* 10(5):701-707; 1975.

Two cases involving frank ulceration of a gastric tube in children are reported. A 3-yr-old girl sustained a severe esophageal burn following the ingestion of liquid lye. A reverse gastric tube, positioned behind the root of the left lung, was constructed to bypass the strictured esophagus, and the child resumed p.o. feedings and rapidly gained weight. Postoperative barium studies showed some redundancy of the tube in the chest above the diaphragm, but there was an unimpeded flow of barium into the stomach. A contrast study performed 1 yr later, when the patient had developed persistent hematemesis, showed an ulcer crater with radiating edematous folds in the posterior redundant portion of the gastric tube, as well as delayed emptying of the tube through the diaphragm. Her symptoms resolved following treatment with a standard antacid regimen and elevation of the head of the bed. An 18-month-old boy also developed an esophageal stricture after ingesting lye. The esophagus was diverted, the esophagogastric junction was transected and oversewn, and a retrosternal gastric tube was constructed to bypass the destroyed esophagus. Two months later, the patient experienced hemorrhage from the tube through a persistent cutaneous fistula at the cervical anastomosis. The anastomosis was stenotic and refractory to dilatation. A barium study showed narrowing of the gastric tube at the diaphragm. The tube was removed, replaced beneath the sternum, and reanastomosed in the neck. Six months later, a follow-up esophagogram showed stricture and ulceration in the midportion of the tube. The gastric tube was abandoned, and a colon interposition was carried out through the chest. The patient has done well since. It is important to recognize early ulcer formation by serial radiographs throughout the childhood years. While redundancy and partial obstruction with impaired drainage of the tube appear to be etiologic factors, distension of the transposed antrum may lead to hyperacidity and may play a role in ulcerogenesis. A course of dietary and antacid therapy may heal the ulcer, but surgical revision of the tube may be necessary.

8732 BENIGN GASTRIC ULCER WITH "CRESCENT" (QUARTER MOON) SIGN.

(Eng.) Han, S. Y.; Witten, D. M. (Univ. Alabama Sch. Medicine, Birmingham, AL 35233). *Radiology* 113(3):573-575; 1975.

Three cases of benign gastric ulcer with Nelson's "crescent sign" (quarter moon) are reported, with emphasis on the characteristic fluoroscopic and radiographic findings. A 36-yr-old woman was hospitalized with a 1-month history of anorexia and weight loss and a 1-week history of pain in the left lower quadrant of the abdomen. An ill-defined tender mass was palpated in the left lower quadrant, and the hematocrit was 25%. Barium examination revealed a large collection of barium in a quarter-moon-shaped crater on the greater curvature of the antrum. At surgery, a large ulcer crater measuring 10 x 15 cm was found, with the transverse colon, omentum, and transverse mesocolon adherent to it. Duodenostomy was carried out, together with excisio of the ulcer, which proved benign. A 50-yr-old woman was hospitalized with a short history of weak ness, passage of black stools, and vomiting of bright red blood. Two years previously, she had undergone cholecystectomy, common duct exploration, and sphincterotomy. The hematocrit was 19%, and a gastrointestinal series revealed two ulcers on the greater curvature of the antrum. The collection of barium within the larger crater was concave toward the lumen and convex away from the lumen. The smaller and distal ulcer was in the pyloric antrum. Both showed inflammatory tissue with no evidence of malignancy. A 50-yr-old man presented with a 2-day history of hematemesis. He was a heavy drinker and had a 25-yr history of epigastric discomfort. The liver was palpable below the costal margin, the hematocrit was 30.2%, and the hemoglobi was 10 g/100 ml. Barium examination disclosed a large crater on the greater curvature of the antrum with a "crescent sign." The ulcer was benign. In all three cases, the edema of the mucosa overhangin the ulcers was so extensive that the orifice of the crater was almost occluded, and gradual or delayed filling of the crater occurred during barium fluoroscopy. Undermining and edema of the mucosa aroun the crater appears to be reliable evidence of a benign ulcer. Care must be taken to avoid confusio of the crescent sign of a benign gastric ulcer with Carman's meniscus sign of a malignant ulcer.

8733 ENDOSCOPIC ELECTROCOAGULATION OF BLEEDING GASTRIC ULCERS IN INOPERABLE PATIENTS.

(Ger.) Bossart, R.; Gyr, N.; Thurnherr, N. (Kanton spital, CH-4000 Basel, Switzerland). *Z. Gastroenterol.* 13(5):526-528; 1975.

Experiences with endoscopic electrocoagulation (EC) in five geriatric patients with inoperable bleeding gastric ulcers are reported. Localization was either infracardial or supra-angular. Four patient were in hypovolemic shock; all were acutely anemic, with a bleeding duration of 3-9 days. All were cardiac deficient or had decompensated liver cirrho sis. Hemostasis was achieved in four patients. In another patient with gastric polyposis, a massive polyp bleeding from erosion was successfully electr coagulated. Superficial EC of gastric ulcers is often successful and represents an alternative in patients at high surgical risk; it can provide time for further clarification or risk of optimizat

8753 THE INFLUENCE OF ORALLY APPLICABLE ANTIBIOTICS ON THE ACTIVITIES OF HUMAN ENTEROKINASE AND DISACCHARIDASES.

(Ger.) Niessen, K. H.; Sayer, T.; Schunder, E. (Univ.-Kinderklinik, Rumelinstr. 23, 7400 Tubingen, W. Germany). *Arzneim. Forsch.* 26(6):1216-1221; 1976.

The effect of 14 different antibiotics on the enterokinase (EK), lactase (LT), saccharase (SH), and isomaltose (IM) activities of human intestinal mucosa is discussed. All tests were performed on duodenal mucosa sectioned immediately after autopsy, with antibiotic concentration that were 50% inhibitory of enzyme activity. Phenoxymethylpenicillin inhibited EK at 2.1×10^{-2} M but not LT, SH, or IM at 3×10^{-2} M. α-Phenoxypropylpenicillin affected EK at 4.8×10^{-2} M and LT at 1.35×10^{-1} M. EK was inhibited by 1.3×10^{-2} M, SH by 6.5×10^{-2} M, IM by 7.5×10^{-2} M, and LT by 5.5×10^{-2} M of 5-methyl-3-phenyl-4-isoazolylpenicillin. SH, IM, and LT were not affected by 1×10^{-1} M α-aminobenzylpenicillin, but EK was inhibited at 5.0×10^{-2} M. 7-(2-Thienylacetamido)cephalosporin affected EK at 1.5×10^{-3} M, SH at 3.6×10^{-2} M, IM at 5.0×10^{-2} M, and LT at 2.4×10^{-2} M (100% inhibition). EK was inhibited by 3.4×10^{-2} M of 7-(D-α-amino-α-phenylacetamido)-3-methyl-3-cephem-4-carboxylic acid, but 1.0×10^{-3} M of 6-deoxy-5-hydroxytetracycline arrested EK and 2.0×10^{-2} M, 1.2×10^{-2} M, and 1.1×10^{-4} M inhibited SH, IM, and LT, resp. Neomycin-B sulfate was inhibitory of EK, SH, IM, and LT at 3.24×10^{-4} M, 3.2×10^{-1} M, 1.6×10^{-1} M, and 3.25×10^{-1} M, resp. Gentamycin sulfate and polymyxin-E sulfate did not affect SH, IM, or LT at 1×10^{-1} M or 1×10^{-3} M, resp., but it did inhibit EK at $1.45\text{-}1.83 \times 10^{-4}$ M. Polymyxin-B sulfate affected EK, SH, IM, and LT at 1.12×10^{-4} M, 1.2×10^{-1} M, 8.5×10^{-3} M, and 7.0×10^{-2} M, resp. Erythromycin glucoheptonate inhibited EK at 5.1×10^{-3} M. EK was 50%; SH, 20%; IM, 40%; and LT, 20% inhibited by $1.2\text{-}1.26 \times 10^{-1}$ M; resp. The effect of chloramphenicol occurred at molar concentration of 1.26×10^{-2}, 1.1×10^{-1}, 1.3×10^{-1}, and 6.5×10^{-2} for EK, SH, IM, and LT, resp. The inhibitory mechanism was unaffected by cholic acid binding. Neomycin and polymyxin inhibition was competitive; inhibition by the penicillins, cephalosporins, and tetracycline was noncompetitive.

8754 ALPHA-CHAIN DISEASE WITH INTESTINAL INVOLVEMENT. REPORT OF A CASE WITH CLINICAL, HISTOLOGICAL AND IMMUNOLOGICAL RECOVERY AFTER TREATMENT WITH ANTIBIOTICS.

(Fre.) Monges, H.; Aubert, L.; Chamlian, A.; Remacle, J.-P.; Mathieu, B.; Cougard, A.; Arroyo, H. (Hopital Nord, F 13326 Marseille Cedex 3, France). *Arch. Fr. Mal. App. Dig.* 64(3): 223-231; 1975.

The case history of a patient with intestinal involvement of alpha-chain disease is detailed. A 34-yr-old man presented with an acute malabsorption syndrome following a 3-yr history of diarrhea and intermittent abdominal pain. Hepatosplenomegaly was absent and hepatosplenic function was normal. The steatorrhea was 50 g fatty acid/day. The sodium level was 138 mEq/l; potassium, 3 mEq/l; chloride, 90 mEq/l; calcariuria, 34 mg/l; phosphoremia, 26 mg/l; and total cholesterolemia, 1.04 g/l. Barium ingestion showed an abnormal distention of some je nal and ileal loops and jejunal mucosal folds. Biopsy showed either the absence of villi or enlar villi in various jejunal segments. The lamina pr pria was densely infiltrated, predominantly by ATP ase-rich plasmocytes, with a discrete muscularis mucosae infiltration; the submucosa was unaffected Gastric and rectal biopsies were negative. Serum immunoglobulin assay found elevated immunoglobulin A (IgA, 580 mg/100 ml), but normal IgG and IgM. Immunofluorescence of the jejunal sections showed a strong cytoplasmic response to IgA antiserum in the lymphoid cells of the lamina propria. Ampicillin (2 g/day, i.m.), tetracycline (1.5 g/day, p.o. and nystatin (3×10^6 U/day, p.o.) led to clinical amelioration. The serum IgA was normalized (365 100 ml). Indirect immunofluorescence of the lymp plasmocytic elements in the lamina propria showed a reduced level of IgA relative to normal mucosa and the presence of cells containing light kappa- or lambda-chains similar in quantity to normal cells. Within 6 months the patient was considere clinically, histologically, and immunologically cured. The karyotype showed the presence of a 14 + marker, which was not present in siblings or offspring. HL-A8 was positive for a brother but not for the patient.

8755 THE ROLE OF ANGIOGRAPHY IN THE MANAGEME OF INTESTINAL CARCINOID.

(Eng.) Strasberg, Z.; Hyland, J.; Salem, S.; Wilderspin, K.; Tuttle, R. J. (St. Joseph's Hosp., 50 Charlton Ave East, Hamilton, Ontario, Canada). *Angiology* 26(8) 573-583; 1975.

The angiographic features in two cases of carcino tumors of the intestine are presented. A 74-yr-o woman was hospitalized with a 4-yr history of int mittent diarrhea associated with crampy abdominal pain. Physical examination revealed an enlarged, firm, irregular liver with many nodules, a murmur over the pulmonary valve, and evidence of right heart failure. Serum albumin was 2.5 g%, alkalin phosphatase was 150 U, and urinary 5-hydroxy-indo acetic acid was 20 mg/24 hr. An abdominal series was consistent with partial small bowel obstructi and a liver scan revealed multiple areas of decreased uptake. Selective superior mesenteric angiography revealed narrowing of the major ileocolic branches of the superior mesenteric artery, poor to moderate accumulation of contrast, poor filling in the venous phase, and a stellate appea ance of the vasa recta and arcade branches of the superior mesenteric artery. Selective hepatic arteriography revealed multiple vascular nodules the liver and tumor vessels, with the tumor blush persisting into the capillary phase. At surgery, an intramural nodule, later confirmed as a carcin tumor, was identified about 4 cm from the ileo-ce valve; the liver was studded with metastases, and a stricture of the bowel was confirmed. A 28-yr- woman presented with a 4-yr history of hemorrhagi rash, episodic flushing and diarrhea, and a tende to cyanosis on exposure to cold. The liver was enlarged and nodular and the urinary 5-hydroxy-

leacetic acid was 112 mg/24 hr. Angiography
aled several vascular lesions in the liver,
ding of the intrahepatic branches, a vascular
le to the left of the midline, and a tumor blush
persisted into the venous phase. At surgery,
rcinoid lesion was identified at midileum, with
iple metastases in the liver and involvement of
regional nodes. In conjunction with previously
rted cases, these indicate that relatively
ific angiographic criteria exist for the detec-
of the primary tumor. Angiography can also be
ul for localizing hepatic metastases and the
ries of hepatic blood supply. Angiography is
cated in patients with intestinal carcinoid
r to surgery or radiotherapy.

USE OF JEJUNAL NEOMUCOSA IN THE TREATMENT
OF THE SHORT GUT SYNDROME IN PIGS. (Eng.)
ington, H. B.; Tumbleson, M. E.; Ternberg, J. L.
hington Univ. Sch. Medicine, 4960 Audubon Ave.,
Louis, MO 63110). *J. Pediatr. Surg.* 10(5):617-
1975.

est the effectiveness of the jejunal neomucosa
meliorating the short gut syndrome, young Sin-
r (S-1) miniature pigs underwent small bowel
ction and subsequent patching (6 weeks later) of
junal incision with intact colon. The small
l was examined grossly and histologically at
psy 28 weeks after the original resection. The
age length of bowel remaining after resection
182 cm in the control pigs (no subsequent patch-
with colon) and 185 cm in the experimental
als. At sacrifice, the small bowel was signifi-
ly longer in the controls (268 cm versus 236
There was no disproportionate dilatation in
small intestine proximal to the patched jejunum,
the small bowel diameter doubled from 1.5 to
cm in both groups. Most blood values were normal
oth groups, although variations from normal in
blood urea nitrogen and inorganic phosphorus
ls were present in both groups within 4-6 weeks
esection. Within 11 weeks of patching, however,
experimental animals had gained significantly
weight than the controls, and this difference
maintained throughout the experiment. The new
sa in the experimental animals grossly resembled
adjacent normal mucosa, although somewhat flat-
d areas and a few ulcerated areas were focally
ent. Histologically, there were changes suggest-
of chronic irritation: increased goblet cells,
short and blunted villi, areas of increased
t:villus ratio, and a few areas of gastric meta-
ia.

DUODENAL-JEJUNAL ULCERS AND RECURRENT
HEMORRHAGE: DIAGNOSTIC VALUE OF TOTAL
ROSCOPY. (Eng.) Conley, D. R.; Feffer, M.;
, H. (Cedars-Sinai Medical Center, Mt. Sinai
. Div., 8720 Beverly Blvd., Los Angeles, CA
3). *Am. J. Dig. Dis.* 20(9):876-881; 1975.

se of recurrent, life-threatening gastrointes-
l hemorrhage from multiple jejunal ulcers is
rted. A 42-yr-old woman developed melena while
convalescing from aortic valve prosthetic surgery. Two months later, the patient noted hematochezia, and a posterior-wall duodenal ulcer was found at laparotomy. A vagotomy and pyloroplasty were performed, and the bleeding stopped. The bleeding recurred 2 yr later, and during the ensuing 9-month period, the patient was hospitalized on six occasions because of melena and anemia. Repeat gastrointestinal x-rays were negative, and physical and laboratory findings were normal. A Cantor tube was inserted into the first portion of the duodenum and allowed to transit through the small intestine. Midway through the jejunum, the small bowel aspirate became benzidine-positive, suggesting that the bleeding site was the small intestine. A new colonoscopy technique was used. The fiberoptic colonoscope was introduced into the sigmoid colon at the time of operation and was passed through the ileocecal valve. The small intestine was then guided over it, allowing the visualization of the entire small intestinal mucosa. This technique revealed multiple hemorrhagic punched-out ulcers in the midportion of the jejunum. These ulcers extended into the third and fourth portions of the duodenum, but no lesions of the esophagus, stomach, or duodenal bulb were noted. There were no serosal abnormalities of the small intestine. The involved section of the jejunum was resected, and an end-to-end anastomosis was performed. Three months later, multiple jejunal ulcerations were found distal to the previous line of anastomosis, and multiple duodenal ulcerations were also noted. Resection of the duodenum, distal stomach, and involved jejunum failed to prevent recurrence of the bleeding episodes. Microscopically, the jejunal ulcers consisted of a bland, noninflammatory disruption of the mucosa with focal subjacent submucosal hemorrhage. There was virtually no exudate; angitis, vascular thrombosis, granuloma, or foreign material was not identified; and cultures and stains for amyloid, fungi, and acid-fast organisms were negative. The cause of the ulcerations in this case is unknown.

Malabsorption

782 QUANTIFICATION OF THE THREE-DIMENSIONAL STRUCTURE OF JEJUNAL MUCOSA IN HEALTHY UBJECTS AND PATIENTS WITH CELIAC DISEASE. (Ger.) iecken, E. O.; Sahlfeld, M.; Lorenz-Meyer, H. Medizinische Universitatsklinik, 355 Marburg/Lahn, annkopffstr. 1, W. Germany). *Dtsch. Med. Wochenschr.* 01(2):51-53; 1976.

icrodissection data on the three dimensional strucure of intestinal mucosa in healthy persons and atients with celiac disease (CD) are presented. he relation between resorbing mucosal surfaces and illi height is more closely defined. Jejunal iopsies from 10 healthy persons and from 4 treated nd 3 untreated CD cases with total or partial illous disappearance were prepared and examined tereomicroscopically. A villous surface below the igament of Treitz average 0.455 mm^2, while the nner surface of villi in the superior jejunum was reater by a factor of 8.3. In untreated CD, the nner surface fell to one per unit of area, the umber of crypts per mm^2 was reduced about 59%, and he crypt depths were increased. In treated sprue, he number of villi was less than normal, but the atio of crypts per villi was within normal range 10.2); crypt depth was nearly doubled. The number f mitoses per crypt was elevated in CD. A highly ignificant positive linear correlation could be stablished between mucosal surface and villous eight, and a negative linear correlation could be stablished between number of mitoses and mucosal rea in healthy and CD intestines. Since villous eight and resorption potential were correlated ositively in earlier studies, it is now possible o infer from villous height to the size of the esorbing mucosal area in biopsy specimens.

783 ENTEROPATHY AND PRIMARY IgA DEFICIENCY. REPORT OF A CASE WITH PROGRESSIVE ATROPHY THE INTESTINAL MUCOSA. (Fre.) Dedieu, P.; Le odic, M. F.; Simon, J.; Le Mevel, B.; de Lisle, L.-.; Miniconi, P. (Hopital Saint-Jacques, F 44200 antes, France). *Arch. Fr. Mal. App. Dig.* 64(4): 47-357; 1975.

The case history of a patient with malabsorption syndrome and primary immunoglobulin A (IgA) deficiency is examined. A 49-yr-old woman with a history of chronic diarrhea and bronchial infection gave evidence of malabsorption, moderate steatorrhea and diminished or absent levels of IgA. Fibroscopy showed duodenal pseudoploidy. The patient's condition was refractory to gluten diets and corticoid therapy. Laparotomy showed an infiltrated jejunal loop, mesenteric adenopathy, and splenomegaly. Jejunal histology showed atrophied villi. Liver function was normal, coproculture negative, and thoracic and abdominal radiology normal. There was diffuse atrophic gastritis. Barium transit found duodenal lacunae. Subsequent jejunal biopsies confirmed progressive total or subtotal villous atrophy without crypt hypertrophy, but with diffuse lymphoid hyperplasia, no plasmocytes, eosinophilia, immature lymphocytosis, and histiocytosis. There was no evidence of autoimmune involvement. In the lamina propria, there was a complete absence of plasmocyte response to IgA and a diminished reaction to IgM. The effect of parenteral vitamin B_{12} was transient. It is suggested that IgA deficit renders the intestinal mucosa more permeable to certain antigens, predisposing the patient to immune reactions in the lamina propria that cause villous atrophy.

8784 WHIPPLE'S DISEASE. HEPATIC GRANULOMATOUS LOCALIZATIONS DETECTED BY LIVER BIOPSY. (REPORT OF TWO CASES). (Fre.) Cornet, A.; Barbier, J.-Ph.; Henry-Biabaud, E.; Malvy, J.-P.; Benisty, H.; Carnot, F. (Hopital Laennec, 42, rue de Sevres, F 75340 Paris Cedex 7, France). *Ann. Med. Interne (Paris)* 127(2):139-146; 1976.

The systemic involvement of Whipple's disease is examined in two case histories. A 53-yr-old man presented with anorexia, fatigue, epigastric heaviness, low grade fever, microcytic anemia, eosinophilia, and elevated sedimentation rate. Liver function was normal. Liver biopsy revealed nonnecrotic, tuberculoid granulomatosis, refractory to isoniazide, rifampicin, and ethambutol. There was a suspicion of abnormality in the first jejunal loop and evidence of steatorrhea. Jejunal biopsy revealed infiltration of PAS-positive macrophages and deformed villi. PAS-positive inclusions were confirmed for the liver, ganglia, and rectal mucosa. Intestinal involvement extended to the pylorus. Tetracycline (2 g/day, p.o.) was begun, and regression of functional signs was manifest in 2 weeks. A 52-yr-old man with a history of arthropathy developed episodic radiating abdominal pain with fever, followed by persistent diarrhea. Barium studies showed jejunal dilatation. Slight anemia, an elevated sedimentation rate, and prominent steatorrhea were the most significant paraclinical irregularities. Intestinal biopsy found an excess of PAS-positive granular macrophages infiltrating and distorting the villi. Transaminase levels were normal. Liver biopsy showed a granulomatosis. Ampicillin, 2 g/day, i.m. and 2 g/day, p.o., led to complete symptomatic regression. The pathogenesis of Whipple's disease is concluded to be associated with an abnormality in marcophage function.

LARGE INTESTINE

8791 COLON AND RECTUM. (Eng.) Cutler, S. J. *In: Cancer Epidemiology and Prevention.* (Springfield: Charles C. Thomas): pp. 375-385; 1976.

The incidence rates of colonic and rectal cancers between the late 1940's and the 1960's were obtained from the tumor registry in Connecticut and from seven National Cancer Institute surveys of cancer occurrence in selected metropolitan areas of the United States and compared. Both sets of data indicated that between the late 1940's and late 1960's, the incidence of colon cancer increased by about 25% in white males, but remained at the same level in white females. Both sets of data indicated a decrease in rectal cancer; the Connecticut data showed incidences of 20.1/100,000 and 19.1/100,000 in men and 13.0/100,000 and 12.4/100,000 in women during the periods 1945-1949 and 1965-1968, resp. The seven surveys showed incidences of 19.8/100,000 and 15.5/100,000 in men in 1947 and 1969, resp., and 13.3/100,000 and 9.4/100,000 in women, resp. The data from the seven surveys indicated that between 1947 and 1969 the incidence of colon cancer has doubled in both male and female Negroes. Thus, among men, the increase was appreciably larger in Negroes; among women, ther was a larger increase in Negroes and no increase in whites. As a result of the larger increases among Negroes, the incidence of colon cancer is now at th same level in whites and Negroes (29.6 and 25.0/100,000 in white men and women, resp.; 26.2 and 24. 100,000 in Negro men and women, resp.). The change in the incidence of cancers of the rectum was simil in white and Negro women--down from 13 to 9/100,000 Among men, however, the incidence rate decreased among whites (19.8/100,000 to 15.5/100,000), but di not change among Negroes (12.0/100,00 in 1947 and 1 100,000 in 1969). The incidence rates of rectal an colonic cancer among both Negroes and whites were lower in the southern cities than in the northern or western cities. The observed lower incidence rates in the South, the temporal changes in inciden level in different geographic areas within the Unit States, and the unequal changes in incidence among

ites and Negroes all suggest the influence of en-
ronmental factors.

92 EXFOLIATIVE CYTOLOGY OF THE COLON. (Fre.)
Cabre-Fiol, V.; Aran-Suau, J.; Pujol-Pi,
; Germa, J. R.; Vilardell, F. (Hopital de la Santa
iz y San Pablo, Barcelona 13, Spain). *Ann. Gastro-*
terol. Hepatol. 11(3):235-243; 1975.

periences with exfoliative cytology (EFC) in com-
rison to biopsy, endoscopy, and radiology for the
agnosis of colon carcinoma (CC) are discussed.
C was positive for CC in 87% of 34 confirmed cases,
mpared to 93% for biopsy, 84% for endoscopy, and
% for radiology. In cases of significant inflam-
tory exudate in hemorrhagic rectocolitis, EFC
utinely confirmed the endoscopic evidence. EFC
particularly valuable in rectocolitis and Crohn's
sease of long duration, with their high frequency
CC. In six patients with recurrent colitis, EFC
und cell atypia in four smears and biopsy was
sitive in three. EFC was positive in seven and
opsy in four smears of nine chronic colitis cases.
seven clinical cures, EFC and biopsy were positive
five and four smears, resp.; the persistence of
ypical cells in cured patients is noteworthy.
C is recommended when endoscopic biopsy is nega-
ve.

)3 HYPOTONIC EXAMINATION OF THE COLON WITH
GLUCAGON. (Eng.) Gohel, V. K.; Dalinka,
K.; Coren, G. S. (Thomas Jefferson Univ. Hosp.,
iladelphia, PA). *Radiology* 115:1-4; 1975.

use of glucagon (1-2 mg) to relieve spasms during
otonic examination of the colon was studied in
patients. Glucagon was administered i.m. (90
es) or i.v. (13 cases) 5-8 min before the examina-
n or when an area of narrowing or obstruction was
ountered during the study. Glucagon was uniform-
successful in relieving functional spasm. Only
e patients suffered transient nausea, and no other
e-effects were encountered. In comparison with
pantheline bromide (Pro-Banthine), glucagon offers
er problems in terms of side-effects and contra-
ications. The only known contraindications with
cagon are pheochromocytoma, insulinoma, and war-
in-induced hypothrombinemia. The exact mechanism
the hypotonic effect of glucagon has not been
ermined.

4 VILLOUS ADENOMA OF THE LARGE BOWEL; BENIGN
AND MALIGNANT. (Eng.) Bresnihan, E. R.;
pkins, K. C. (Leeds [St. James's] Univ. Hosp.,
ds, England). *Br. J. Radiol.* 48(574):801-810;
5.

radiologic appearances of 14 villous adenomas
double contrast barium enema examination are re-
ted. Eleven adenomas were benign and 3 were car-
omatous. Two of the tumors occurred in the de-
nding colon and one each occurred in the ascend-

ing colon and transverse colon; the rest were found in the rectum or sigmoid colon. Most of the tumors were between 3 and 8 cm at diagnosis. The radiologic appearance in the villous adenomas was of a large intraluminal filling defect with a fine reticular lace-like pattern; the more solid lobulated tumors showed a coarser mosaic pattern. In one case, the lesion was barely discernible in the proximal transverse colon, and its appearance on the radiograph was mistaken for a coating of fecal material. In another case, basal indentation was present in four cases, all of which were benign, while only one of the malignant tumors showed unequivocal radiological evidence of malignancy, i.e., narrowing of the lumen, with constant rigid bowel wall and mucosal destruction. Large size was not a reliable indicator of malignancy. Of the 14 cases studied, additional neoplasms were diagnosed on the barium enema examination in 7. There were three cases of synchronous carcinoma, one with a previous history of resections for two large bowel carcinomas, two cases of multiple adenomatous polyps, and one case involving a second villous adenoma. The detection of any rectal or colonic neoplasm, especially a villous adenoma, should be followed by examination of the whole large bowel by double contrast barium enema and/or colonoscopy.

8795 VILLOUS TUMOR OF THE RECTUM: A CASE WITH SEVERE HYDROELECTROLYTIC DEPLETION. ULTRASTRUCTURAL STUDY, AND THE PRESENCE OF CARCINOEMBRYONIC ANTIGEN AND IMMUNOGLOBULINS IN THE MUCUS. (Fre.) Bekhti, A.; Boniver, J.; Jacquet, N. (Departement de clinique et de pathologie medicales, Universite de Liege, Liege, Belgium). *Acta Gastroenterol. Belg.* 38(5/6):227-236; 1975.

The ultrastructure and secretory behavior of a rectal villous tumor were analyzed in an elderly woman who presented with a history of rectal polyps, diarrhea, abundant mucus secretion, nausea, vomiting, and dehydration. The sphincter was atonic and a mass was palpable. Rectoscopy found a tumor suspended in viscous fluid that was diagnosed histologically as villous adenoma. The secretory volume varied between 1.5 and 2.5 l/day. Immunoglobulin A (IgA) was found in the mucus fluid, along with high levels (1,000 ng/ml) of carcinoembryonic antigen (CEA). An abdominoperineal excision was performed. No hepatic, peritoneal, or nodal involvement was found. The mass was 19 by 7 cm, with fringes 8-9 mm long, and it encroached on the rectal bulb. The patient's condition improved dramatically and has remained satisfactory for 2 yr. The epithelium of the villosities resembled normal rectal mucosa. The interstitial tissue showed only moderate lymphoplasmocytic infiltration. Cell atypia occurred at the anal margin with nuclear stratification and numerous mitoses. Ultrastructurally, the Golgi bodies and endoplasmic reticulum were well-developed and the nuclei were active in the otherwise unexceptional surface epithelial cells. Plasmocyte IgA was detected on the tumor fringes. IgM and IgG were negative. The large amount of mucus was attributed to the great surface area of the tumor rather than to cell dysfunction.

8796 COLITIS PROXIMAL TO OBSTRUCTING COLONIC CARCINOMA. (Eng.) Tietjen, G. W.; Markowitz, A. M. (Columbia Univ., Coll. Physicians and Surgeons, 622 West 168th St., New York, NY 10032). *Arch. Surg.* 110(9):1133-1138; 1975.

The cases of five patients with nonspecific colitis proximal to an obstructing colonic carcinoma are presented. The first patient, a 75-yr-old diabetic man, had a carcinoma involving the entire wall of the descending colon, which was discovered at laparotomy following a 10-month history of lower abdominal pain and constipation. In the first 9 cm from the proximal margin, the mucosa exhibited an exudative colitis; a resection of the sigmoid colon was performed with a primary anastomosis. The patient made an uneventful recovery, but died 3.5 yr later due to metastatic disease. The second patient, a 72-yr-old man, presented with acute abdominal pain. An obstructing carcinoma of the midsigmoid colon, involving the serosal surface, was found. The mucosal surface of the proximal bowel was covered with a gray exudative pseudomembrane with several thickened inflammatory nodules. A left-sided colectomy with colocolostomy was performed; the patient recovered uneventfully, but died 2 yr later of metastatic disease. The third patient was a 36-yr-old woman with a 6-week history of abdominal pain, nausea, vomiting, and constipation. A completely obstructing sigmoid carcinoma was found, in addition to three proximal irregular ulcers (2 of which were perforated) and transmural inflammation of the colonic wall. The patient shows no further evidence of carcinoma after undergoing transverse and sigmoid colostomies. Abdominoperineal resection was performed in the fourth patient, a 59-yr-old woman, for a large fungating rectal carcinoma with 80% constriction of the lumen. She had presented with diarrhea and bloody stools. At 18 cm from the anal verge, there was a fibrous constriction showing fibrosis and infiltration of the submucosa and lamina propria, with lymphocytes and plasma cells. The patient died 16 months later of metastatic disease. The last patient, a 74-yr-old diabetic woman, presented with abdominal pain, vomiting, bloody diarrhea, and peritoneal signs in the lower abdomen. A constricting rectosigmoid carcinoma and a proximal segment of acute necrotizing colitis with early perforation were found; the carcinoma and colitis were separated by a zone of normal tissue. If colitis is present in the gross specimen, a more extensive resection is suggested. Consideration should be given to exteriorization of the colonic limbs or anastomosis with a proximal diverting colostomy.

LARGE INTESTINE

Ulcerative Colitis

8839 RESPONSES TO DRUG THERAPY IN ULCERATIVE COLITIS: EVALUATION BY RECTAL BIOPSY AND HISTOPATHOLOGICAL CHANGES. (Eng.) Korelitz, B. I.; Sommers, S. C. (Lenox Hill Hosp., 100 East 77th St., New York, NY 10021). *Am. J. Gastroenterol.* 64(5):365-370; 1975.

The healing process of the large intestinal mucosa in ulcerative colitis was studied using rectal biopsy material from 363 cases of noninfectious inflammatory bowel disease and 50 controls. Histological changes were studied as the mucosa responded to drug therapy, with salicylazosulfapyridine, prednisone, 6-mercaptopurine and combinations of these agents. There was no statistically significant difference in the histologic alterations of 43 sigmoidoscopically positive untreated ulcerative colitis cases when compared to 115 sigmoidoscopically positive treated ulcerative colitis cases. Significantly fewer crypt abscesses ($p<0.025$) and more mucosal edemas ($p<0.001$) were found in the 55 patients with negative sigmoidoscopy after thera py than compared to the 115 sigmoidoscopy-positive patients. Drug combinations offered no identifiabl different histologic alterations, either when compared to each other or to each drug used alone. However, the overall histologic changes were signif cantly fewer after salicylazosulfapyridine than after either prednisone or 6-mercaptopurine therapy The results confirm that clinical remission in ulce ative colitis is not necessarily accompanied by resolution of the inflammatory process. Histopatholo gy of rectal biopsies is not significant for compar ing the responses of ulcerative colitis to individual drug therapy.

8840 LICHEN PLANUS AND ULCERATIVE COLITIS. (Eng.) Wyatt, E. H. (Dept. Dermatology, Hull Royal Infirmary, Hull HU3 2JZ, England). *Br. J. Dermatol.* 93(4):465-468; 1975.

cases of three patients with ulcerative colitis
an eruption resembling classical lichen planus
presented. The first patient, a 36-yr-old man,
plained of diarrhea and patchy nonpruritic rash.
moidoscopy showed pus, contact bleeding, and a
iable vascular pattern. Ulcerative colitis was
onstrated in the distal transverse colon by radio-
phy. The hemoglobin was 11.9%, and the WBC count
6,600, with toxic granulation in the polymorphs.
serum mucoprotein was 354 mg/ml. Despite treat-
t with salicylazosulfapyridine, methyl cellulose,
prednisolone enemas, the eruption increased.
ermatological examination revealed multiple
ple polygonal papules with Wickham's striae.
l lesions of lichen planus were seen. A good
ponse was obtained with a topical fluocinolone
tonide cream (0.2%). Case 2, a 45-yr-old man,
eloped a blistering, itchy eruption on the extrem-
es, followed by diarrhea with blood, mucus, and
ominal pain. Sigmoidoscopy showed a granular
friable mucosa with chronic inflammatory cells
the lamina propria. The serum mucoprotein was
mg/ml. Although he responded to treatment with
dnisolone enemas and methyl cellulose, he had
ermittent diarrhea and developed widespread lichen
nus of the limbs and trunk. The skin histology
wed slight hyperkeratosis and epidermal hyper-
sia. The eruption settled after 1 yr of treat-
t with fluclorolone acetonide 0.025% cream.
e 3, a 51-yr-old woman, developed diarrhea, and
ium enema examination revealed a loss of haustra-
n. Serum mucoprotein was 177 mg/ml. Her symp-
s temporarily responded to treatment with systemic
roids and p.o. salicylazosulfapyridine. When
symptoms recurred, sigmoidoscopy revealed an
ormal red granular mucosa and ulcerative colitis.
rash gradually faded following 15 months of
atment with flucortolone acetonide 0.025% cream.
author rules out the possibility that the skin
ease in these patients is due to drug therapy.
ce both rash and ulcerative colitis are character-
d by low epithelial cell turnover and increased
l death followed by cell infiltration at the
ement membrane, the skin and gut changes in
se patients could have a causal rather than a
tuitous relationship.

1 THE ALTERNATE COMPLEMENT PATHWAY IN INFLAM-
MATORY BOWEL DISEASE. QUANTITATION OF THE
PROACTIVATOR (FACTOR B) PROTEIN. (Eng.) Fein-
ein, P. A.; Kaplan, S. R.; Thayer, W. R. (Dept.
icine, Brown Univ., Providence, RI). *Gastroente-
ogy* 70(2):181-185; 1976.

C3 proactivator (C3PA) protein, a component of
alternate complement pathway, was measured in
normal volunteers and compared with the C3PA
ers of 14 patients with Crohn's disease (CD), 26
h ulcerative colitis (UC), and 5 with UC treated
surgery. The normal value was 74% (range, 43-108%),
le the UC patients had a mean of 95% (range, 69-
%) and the CD patients had a mean of 119% (range,
-183%). The differences in mean values were high-
significant ($p<0.001$) when patient groups were
pared with normal subjects or with each other.
en the C3PA titer of CD patients who were doing well or were stable was compared with that of CD patients experiencing an exacerbation, the latter was significantly higher ($p<0.01$). Values for treated CD patients were not significantly different from those for nontreated patients, nor were there significant differences related to type of treatment (salicylazosulfapyridine or steroids). The differences between C3PA titers in UC patients considered stable and in those experiencing exacerbation were significantly different from the normal titer ($p<0.01$ and 0.001, resp.), but not significantly different from each other. Treated and nontreated UC patients did not have significantly different titers of C3PA, nor did the mode of treatment result in any significant differences. The results demonstrate that the disturbance in C3PA metabolism is different for both CD and UC. There is a general derangement in complement metabolism in UC reflected in the abnormal $C'H_{50}$. This general derangement parallels similar abnormalities in the component parts of both the classical (C3, C4) and alternate (C3PA) pathways in CD and UC. In addition, there is a difference in complement metabolism in both classical and alternate pathway components between UC and CD patients in remission.

8847 ANGIOGRAPHY IN ACUTE PANCREATIC TRANSECTION. (Eng.) Soroudi, M.; Bookstein, J. J. (Univ. Michigan Medical Center, Ann Arbor, MI 48104). *Radiology* 115(2):309-311; 1975.

The angiographic features in two cases of acute traumatic transection of the pancreas are reported. A 12-yr-old girl was hospitalized with left upper quadrant pain after being kicked by a horse. Laboratory tests revealed high serum amylase, and a peritoneal tap was trace-positive for blood. Celiac and selective splenic artery injection with a contrast medium revealed multiple small areas of extravasation from the intrasplenic arterial branches. The parenchymal phase revealed some mottling of the spleen with suggestion of an avulsed fragment. There was early filling of the splenic vein, without evidence of displacement or compression. A diagnosis of splenic rupture was made. Laparotomy revealed subcapsular hematoma of the spleen, avulsion of short gastric arteries, complete transection of the distal fourth of the pancreas, and a hematoma involving the tail of the pancreas. Splenectomy and distal pancreatectomy were performed. A 19-yr-old man developed profound weakness, anorexia, weight loss, and ascites after suffering trauma to the back and right flank in an automobile accident. The serum amylase and serum lipase were elevated, the hemoglobin was 10.5 g/100 ml, and an abdominal tap revealed fluid with a high amylase concentration. A celiac and superior mesenteric arteriogram revealed normal pancreatic vessels, with displacement of the superior mesenteric artery to the left; an intrahepatic hematoma was also demonstrated. Surgery revealed a huge pseudocyst of the lesser sac, a larger hepatic hematoma, a fracture of the pancreas at the junction of the body and the head, and complete transection. In both cases, a lack of correlation between the angiographic and operative findings was evident. A possible explanation lies in the apparent fragility of the pancreas, so that transection may occur with little or no intra- or extra-pancreatic hemorrhage. The fact that the normal pancreas stains relatively faintly on angiography also impairs recognition of transection.

8848 RETROGRADE PANCREATIC VENOGRAPHY. AN EXPERIMENTAL STUDY. (Eng.) Rosch, J.; Dotter, C. T. (Univ. Oregon Medical Sch., 3181 S.W. Sam Jackson Park Road, Portland OR 97201). *Radiology* 114(2):275-279; 1975.

The feasibility of retrograde pancreatic venography was explored in 10 anesthetized mongrel dogs using transjugular, transhepatic portal access and a coaxial technique for selective pancreatic vein catheterization. Selective venograms were obtained with 2-sec manual injections of contrast medium (76% Renografin, 0.5-15.0 ml); serial filling was done at two exposures per sec during the injection, with four films at 1-sec intervals thereafter. A detailed autopsy evaluation of the pancreas was then performed. Optimal filling of the catheterized vessel and its branches and sometimes, even anastomoses to other pancreatic vessels were obtained with a deep but unwedged positioning of the catheter tip in the pancreatic vein and an adequate amount of contrast medium. With lesser amounts of contrast medium or with the catheter tip near the venous ostium, the catheterized vein alone was filled incompletely. Larger injections sometimes resulted in a partial penetration of contrast medium into the parenchyma and large injections into small vessels and wedged injections caused an extensive penetration of contrast material into the parenchyma. Wedged injection into a left pancreatic vein caused dense infi tration to much of the left pancreatic lobe, wedge injection into a branch of the pancreaticoduodenal vein infiltrated only a small part of the right pancreatic lobe, and wedged injection into a media venous arcade resulted in diffuse filling of the distal portion of the right pancreas. At autopsy, no changes were found in the areas of the pancreas where only free venography was done, and there was little or no pancreatic parenchymal filling. However, swelling, loss of lobular structure, and foc to-diffuse parenchymal hemorrhages were found in areas of the pancreatic parenchyma infiltrated by contrast agent. Selective catheterization and retrograde pancreatic venography by the transjugular approach may offer improved pancreatic diagnosis when the safety of this method is further demonstrated.

8849 HEMORRHAGE FROM THE PANCREATIC DUCT. STUDY OF SIX PERSONAL CASES AND LITERATURE REVIEW. (Fre.) Vankemmel, M.; Paris, J. C.; L'Hermine, C.; Houcke, M. (Cite Hospitaliere, 5900 Lille, France). *Med. Chir. Dig.* 5(2):83-91; 1976.

Hemorrhage from Wirsung's duct into the gastrointestinal tract is reported in six patients. A 69-yr-old man presented with a 6-month history of epigastric pain, melena, and hematemesis. Celiac-mesente ic arteriography found a small calcified aneurysm i the splenic artery. Examination of the pancreas after splenopancreatectomy also showed a vascular calcification in the Wirsung duct. The diagnosis was wirsungorrhagy (WGR) secondary to a pancreatic lesion of arterial origin. WGR by arterial erosion during pancreatopathy was exemplified in five patients. A 48-yr-old man with chronic pancreatiti (CP) for 10-yr duration presented with epigastric pain, vomiting, melena, and anemia. Laparotomy found the head of the pancreas hypertrophied, corresponding to a hemorrhagic pseudocyst communicating with Wirsung's duct. Surgery in a 36-yr-old man with a history of CP and recent icterus, anemia and melena found a cholestatic liver, denuded gastr duodenal artery, distended gallbladder, and massive cystic necrosis of the pancreatic head and body encroaching on the pancreatic duct. Similar symptoms occurred in a 43-yr-old man with a massive retroperitoneal hemorrhagic focus occupying the entire bed of the pancreatic head and tail due to erosion of the splenic artery. A 30-yr-old man with nearly identical symptomatology was found to have eroded branches of the superior mesenteric and gastroduodenal arteries. A 68-yr-old coronary patient had a massive tumefaction of the pancreatic head, whose inferior segment was a necrotic thrombus communicating with the pancreatic ducts. The

esence of a communication or lesion between Wir-
ng's duct and the gastrointestinal system should
ggest therapy with a dual-aim: stoppage of hemor-
age and eradication of the primary arterial or
ncreatic cause.

58 ULTRASTRUCTURAL STUDIES OF HUMAN ACUTE PANCREATITIS. (Eng.) Taura, S.; Tsunoda,
.; Yoshino, R.; Harada, N.; Akashi, M.; Ito, T.;
uchiya, R. (Nagasaki Univ. Sch. Medicine, 7-1
akamoto-machi, Nagasaki, 852 Japan). *Gastroen-*
erol. Jpn. 10(2):132-140; 1975.

lectron microscopy was used to examine biopsied
ancreatic tissue from a 32-yr-old woman with acute
emorrhagic necrotizing pancreatitis and to compare
ese findings with those from experimental acute
ancreatitis. Pancreatic acinar units were de-
troyed. The acinar lumen was dilated with filling
f fibrillar materials, occasionally containing de-
enerated cellular components or neutrophils. Fi-
rillar material accumulated at the periphery in
e acinar cells. In some acinar cells, this ac-
mulation occupied the entire cell and was accom-
anied by the disappearance of the luminal margin and the mixing of intracellular fibrillar materials with acinar lumen contents. The basal lamina of these acinar units was almost intact. These findings suggest that the lumen contents may penetrate into the acinar cells through the disruption of the luminal margin. This penetration may be one of the factors in the pathogenesis of human acute pancreatitis. The findings in this case differ somewhat from those obtained in studies of experimental acute pancreatitis in that the deposition of fibrillar materials was limited within acinar cells and the site of penetration of luminal content was found at the luminal margin of acinar cells.

8859 ESTIMATION OF PLASMA ESTEROLYTIC ACTIVITY AND ITS IN VITRO INHIBITION BY PROTEINASE INHIBITORS DURING ACUTE PANCREATITIS IN THE HUMAN. (Eng.) Worthington, K. J.; Cuschieri, A. (Dept.

Surgery, Liverpool Univ., P.O. Box 147, Liverpool L69 3BX, England). *Br. J. Exp. Pathol.* 57(2):165-169; 1976.

The plasma esterolytic activity was measured using benzoyl arginine ethyl ester (BAEe) in the peripheral venous blood of 12 patients with acute pancreatitis, 7 normal healthy volunteers, and a contrast group of 10 patients with acute intraabdominal inflammations other than acute pancreatitis. The plasma esterolytic activity was significantly elevated in the pancreatitis group (mean activity= 925 mU/100 ml), in comparison with the activities in controls (275 mU/100 ml, $p<0.01$) and the contrast group (385 mU/100 ml, $p=0.98$). This activity was maximal during the first 48 hr of the illness and remained elevated for a further 8 days thereafter. Aprotinin (2,000 K.I. U/0.3 ml plasma) did not completely inhibit this esterolytic activity (mean inhibition, 82 ± 24%), although it resulted in a more substantial inhibition than either ovomucoid (2 mg; mean inhibition, 34 ± 28%) or soybean inhibitor (2 mg; 51 ± 29%). It is concluded that pancreatic enzymes are released into the circulation during acute pancreatitis and that aprotinin does not completely inhibit this proteolytic activity. This polyvalent proteinase inhibitor should be administered in much higher dosage than that used formerly in acute pancreatitis. The plasma esterolytic activity appears to be of diagnostic value in acute pancreatitis.

8860 COLONIC LESIONS DURING NECROTIZING PANCREATITIS. REPORT OF FOUR CASES.

(Fre.) Leborgne, J.; Pannier, M.; Le Neel, J.-C.; Potiron, L.; Visset, J. (Clinique Chirurgicale A, C.H.U., Hotel-Dieu, place Alexis-Ricordeau, 44035 Nantes Cedex, France). *Ann. Chir.* 30(5):377-383; 1976.

The case reports of one patient with colonic necrosis and three with colonic fistulas secondary to acute pancreatitis are reviewed. A 39-yr-old woman with a history of renal transplantation suddenly developed severe abdominal pain, significant diarrhea, and abdominal distension. An unusually large amount of gas was found in the posterior epiploic region due to colonic perforation at the level of the transverse colon. Necrotizing pancreatitis was found on the body and tail of the organ. A colectomy from the ascending to the sigmoid colon, cholecystostomy, and a splenopancreatic ablation were performed. The patient died postoperatively. At autopsy, steatonecrotic lesions of pancreatic origin were found in the intestinal submucosa and subserosa. In the three patients with hemorrhagic, lithiasic, and pseudocytic necrotizing pancreatitis, postoperative fistulation complicating simple drainage of the pancreatic bed was found. Two of the patients died from hemorrhage and infection. One patient was considered cured after transverse colectomy extending to the angle of the descending colon, pancreatic sequestrectomy, and cholecystectomy. Colonic necroses are ischemic in origin and arise simultaneously with pancreatic lesions. Colonic perforation is secondary and appears as an internal or external fistulation, a deep suppuration, or acute peritonitis.

8861 SEPTIC COMPLICATIONS OF PANCREATITIS.

(Eng.) Grace, S. G.; State, D. (Harbor General Hosp., Torrance, CA). *Br. J. Surg.* 63(3): 229-232; 1976.

The clinical picture, therapy, and prognosis of 20 patients with pancreatic and peripancreatic abscesse are reported, and a case report of a patient with secondary abscess is presented. Nine patients presented with primary pancreatic lesser sac abscesses and 11 with secondary abscesses; 7 patients with primary and 8 or 9 patients with secondary abscesses were alcoholics. Among the patients with primary pancreatic abscesses, the most common presenting complaint was epigastric and upper abdominal pain, occurring in all but two patients. Five patients had abnormal chest films with infiltrates and atelectasis; one patient had a left pleural effusion. Eight patients were explored surgically; the correct diagnosis was suspected preoperatively in only three cases. All patients were treated with nasogastric suction, parenteral fluids, and antibiotics. The abscesses were drained, and Chaffin tubes and/or Penrose drains were left *in situ*. Six patients who underwent surgery had prolonged fever or septicemia. All but one patient with advanced cirrhosis and progressive bronchopneumonia, who was treated conservatively, survived; the average hospital stay was 37 days. Of 11 patients with pancreatic or peripancreatic abscesses that occurred following surgery, 4 had been hospitalized for acute pancreatitis and 3 had a history suggestive of gallbladder disease. Nine patients developed fever and sepsis within 2 weeks of operation; the other two developed symptoms at 3 and 6 weeks after operation, resp. Six patients had a pleural effusion, demonstrated by chest x-ray, and ultrasound demonstrated cystic lesions or an abdominal mass in three patients tested. The diagnosis of abscess was made in all but one patient, who died after portacaval shunt; his symptoms had been thought to represent delirium tremens. All patients except the one in whom the diagnosis was missed were treated with broad spectrum antibiotics. Of nine patients who were surgically explored at an average of 20 days following the initial operative procedure, eight had pancreatic lesser sac abscess, and one had multiple intra-abdominal abscesses with a primary focus in the lesser sac. There were three deaths. Two of these patients had *Candida* in their blood cultures, and three patients had upper gastrointestinal bleeding. Five patients required second drainage procedures for residual pancreatic and peripancreatic loculations. The surviving patients were hospitalized an average of 92 days. The appropriate management for pancreatic abscess, whether primary or secondary, is early recognition and drainage, and it usually involves prolonged hospitalization. Broad spectrum antibiotics are helpful and should be used until blood cultures indicate a specific antibiotic therapy.

LIVER AND BILIARY TRACT

3876 THE ENTEROHEPATIC CIRCULATION OF BILE ACIDS IN MAN. (Eng.) Hofmann, A. P. (Mayo Clinic and Mayo Foundation, Rochester, MN). *Adv. Intern. Med.* 21:501-534; 1976.

The anatomy and physiology of the biliary circulation are reviewed. The chemistry, shared physical versus specific physiologic actions, bacterial interactions, history, physical biotransformations, portal transport, and hepatic uptake of bile acids are discussed; methods for detecting altered bile acid metabolism and disturbances of the enterohepatic circulation of bile acids are also described. In addition, the enterohepatic circulation under the steady state is characterized in detail with regard to the steroid and amino acid moieties. In man, two primary bile acids, cholic and chenodeoxycholic acids, are formed in the liver from cholesterol; the carboxyl group of these bile acids is conjugated in amide linkage with the amino group of glycine or taurine to form four conjugated primary bile acids, cholylglycine, cholyltaurine, chenylglycine, and chenyltaurine. During enterohepatic cycling, the steroid moiety of the primary bile acids is altered; the most important change is 7 α-dehydroxylation, which results in the formation of deoxycholic acid from cholic acid and lithocholic acid from chenic acid. These secondary bile acids are absorbed in part, conjugated in the liver with glycine and taurine, and excreted in bile. All major biliary bile acids can form mixed micelles with polar lipid molecules, which explains the two specific functions of bile acids: to repress cholesterol and bile acid synthesis in the liver and to inhibit sodium absorption in the small and large intestines. In the past few years, certain aspects of the negative feedback regulation of bile acid synthesis by bile acids have been clarified in man. The administration of chenodeoxycholic acid suppresses cholic acid synthesis by about 50%, and the administration of cholic acid also suppresses chenodeoxycholic acid synthesis by about 50%. Bile acids regulate cholesterol syntheis by inhibiting the HMG-CoA reductase or its sis by inhibiting the HMG-CoA reductase or its this process than cholic acid. The idea is emerging that the quality, as well as the quantity, of bile acids passing through the hepatocyte influences cholesterol and possibly, bile acid synthesis. There has been a spectacular increase in the understanding of biliary circulation during the past 5 yr. The mechanism of cell transport of bile acids, the regulation of their synthesis, and the action of bile acids in bile formation are still unknown.

8877 THE INTERMICELLAR BILE SALT CONCENTRATION IN EQUILIBRIUM WITH THE MIXED-MICELLES OF HUMAN BILE.

(Eng.) Duane, W. C. (Veterans Admin. Hosp., 54th St. and 48th Ave. South, Minneapolis, MN 55417). *Biochim. Biophys. Acta* 398(2):275-286; 1975.

The intermicellar bile salt concentration (IMBC) existing in equilibrium with the bile salt-lecithin-cholesterol mixed micelle was studied in human gallbladder bile obtained at cholecystectomy. Equilibrium dialysis was used to measure the IMBC as a function of ionic strength, dilution, and bile salt content of the mixed micelle. The method was validated using data on the cholate-lecithin mixed micelle. Determinations were also made of the bile salt, phospholipid, cholesterol, bile water, chloride, dialyzate protein, and conjugated bile salt concentrations, and the dialysis was repeated using an artificial bile system prepared from pure conjugated bile salts, egg lecithin, and cholesterol. The IMBC of the bile was essentially independent of ionic strength in the range 0.05-0.15 M chloride. Simple dilution of the bile lowered the IMBC, about two-thirds for each twofold dilution, due to a simultaneous decrease in the molar ratio of bile salt:phospholipid in the micelle. Dilution of the micelles with a constant micellar bile salt:phospholipid ratio did not affect the IMBC. There was a linear relation between IMBC and the micellar bile salt:phospholipid ratio, as defined in the dilution studies, in the study range. For a composite of five bile samples, this relation was described by the equation: IMBC=1.27 (bile salt:phospholipid) + 0.538. Data obtained with the artificial bile agreed closely with those obtained with human bile, suggesting that the other constituents of bile did not affect this analysis. These findings may be helpful in understanding micellar cholesterol solubilization in bile.

8878 ANTIGLOBULIN FACTOR IN SERA FROM PATIENTS WITH LIVER DISEASE.

(Eng.) Yasuda, J.; Arai, K. (Natl. Inst. Health, Shinagawa-ku, Tokyo 141, Japan). *Jpn. J. Med. Sci. Biol.* 29(1):1-9; 1976.

An antiglobulin factor, non-neutralizable by human γ-globulin, was demonstrated in the sera of two patients with liver disease. By absorption and elutio techniques, two fractions were differentiated in a serum: one was reactive to rabbit antibody, and the other seemed to be cross-reactive to rabbit and human antibodies. In a double immunodiffusion test, the antiglobulin factor formed a precipitation band with heat-aggregated human immunoglobulin G (IgG), a did rheumatoid arthritis serum. Although the antiglobulin activity to rabbit antibody was demonstrated in both the IgM and IgG fractions, the reactivity to human antibody was localized in the IgM fraction. From its selective reactivity to individual anti-D sera (sensitizers), at least a part of the specificity of the antiglobulin factor must be related to anti-Gm (1), and can be regarded as autoreactive.

8879 CLINICAL SIGNIFICANCE OF SERUM GLUTATHIONE REDUCTASE IN VARIOUS CLINICAL CONDITIONS, ESPECIALLY IN LIVER DISEASES.

(Eng.) Wakui, K.; Kumata, H.; Tadaki, H.; Yamagata, S. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 118(1):17-23; 1976.

Serum glutathione reductase (SGR) activity was measured in various conditions, including acute hepatitis (110 patients), chronic hepatitis (117), liver cirrhosis (47), malignant neoplastic diseases (30), obstructive jaundice (9), and liver cancer (13) to determine its clinical significance. In 42 normal persons, the mean SGR was 21.1 ± 5.8 U/ml. Statistically significant elevations (at the 1% level) in enzyme activity occurred in all conditions; the levels in acute hepatitis, chronic hepatitis, liver cirrhosis, and cholelithiasis were 77.1± 27.6, 37.3 ± 12.4, 43.9 ± 22.0, and 62.0 ± 26.0 U/ml, resp. The mean SGR levels in 10 patients with gastric cancer, 5 with primary liver cancer, 8 with metastatic liver cancer, 4 with pancreatic cancer, and 3 with cancer of the choledochus were 36.5 ±

11.2, 74.4 ± 40.4, 107.5 ± 40.4, 105.0 ± 37.1, and 150.1 ± 34.3 U/ml, resp. In the patients with acute hepatitis, the elevations in SGR correlated significantly with elevations in SGOT ($p<0.01$), SGPT ($p<0.01$), and alkaline phosphatase ($p<0.01$). In chronic hepatitis, no significant correlations were found between SGR activity and the three parameters of liver function. In patients with liver cirrhosis, there was a statistically significant correlation between the elevation in SGR and alkaline phosphatase ($p<0.01$). It is concluded that the determination of SGR is of limited clinical value.

8880 A DUAL RADIONUCLIDE LIVER SCINTIGRAPHY AND ALPHA FETO PROTEIN EXAMINATION APPROACH IN DIAGNOSIS OF HEPATIC DISEASES.

(Eng.) Felizardo, F. O.; Yamasaki, T.; Kusakabe, K.; Tazaki, E.; Miyamae, T.; Miyakawa, T. (Rizal Provincial Hosp., Pasig, Rizal, Philippines). *J. Philipp. Med. Assoc.* 51(1/2):31-37; 1975.

The results of ^{198}Au colloid liver scans in 24 patients were compared with those of ^{67}Ga citrate scans in 49 patients, and the value of scanning in combination with the determination of alpha-fetoprotein in the diagnosis of various hepatic diseases was studied. Each patient received 200-400 μCi ^{198}Au colloid or 1-2 mCi Ga citrate. Seventeen of the 24 ^{198}Au colloid scans revealed a filling defect, and other 5 scans showed a questionable distribution of radioactivity. In 38 of the 49 ^{67}Ga citrate scans, a filling defect was found, and a further 6 scans showed questionable uptake. When the 24 patients who received the ^{198}Au colloid were also subjected to ^{67}Ga citrate scanning, two showed a scan in which the ^{67}Ga citrate distribution in the filling defect found in the ^{198}Au colloid scan was more than that in the surrounding normal liver tissue. Seven additional scans showed that the ^{67}Ga distribution in the ^{198}Au filling defect was the same as in the surrounding normal liver tissue, seven scans were questionable, and eight scans were negative.

8881 SALYCYLAMIDE GLUCURONIDE FORMATION IN LIVER DISEASE AND ITS CHANGE BY DRUGS.

(Eng.) Adachi, Y.; Wakisaka, G.; Yamamoto, T. (Kinki Univ. Sch. Medicine, Osaka 589, Japan). *Gastroenterol. Jpn.* 10(2):120-131; 1975.

The *in vivo* metabolism of salicylamide glucuronide (SAMG) in 0-6-, 6-12-, and 0-12-hr urine samples was measured after oral administration of salicylamide (maximal glucuronide formation was obtained with 1.0 mg salicylamide), in 7 normal subjects, in 51 patients with various liver diseases, and in 19 patients after drug therapy (bucolome, phenobarbital, rifampicin, and phenytoin). The percent of SAMG recovered from the 0-6-, 6-12-, and 0-12-hr urine samples was 71.3 ± 8.3, 33.0 ± 10.0, and 68.4 ± 7.9, resp., in normal volunteers, with 0-0.08% of the total salicylamide appearing as free salicylamide in the 0-12-hr urine sample. Patients with acute hepatitis excreted most of the salicylamide within 6 hr, indicating rapid drug processing. In patients with acute hepatitis, chronic hepatitis, and liver cirrhosis, the percent of SAMG in the 0-6- and 0-12-hr urine samples was 57.2 ± 8.6 and 53.4 ± 8.7 (a slight, but significant decrease), 66.6 ± 10.9 and 63.9 ± 10.7, and 48.6 ± 10.7 and 46.0 ± 10.2, resp. Free salicylamide increased slightly in cases of liver disease (acute hepatitis, 0-0.4% and chronic hepatitis, 0-0.6%). Serum bilirubin levels tended to be inversely correlated with the percent of SAMG. In three of five cases of Gilbert's syndrome, the percent of SAMG remained at a normal level. The percent of SAMG in cases with unconjugated hyperbilirubinemias of other geneses was almost within normal limits. Bucolome (900 mg, p.o.) and phenobarbital (100 mg, p.o.) increased the percent of SAMG in patients with various liver diseases. After rifampicin (450 mg, p.o.) or phenytoin administration, the percent of SAMG of the patients with lung tuberculosis or epilepsy did not surpass that of normal volunteers. Because the percent of SAMG was almost normal in slight unconjugated hyperbilirubinemias, bilirubin glucuronide formation is thought to be more vulnerable than drug glucuronide formation.

8882 TREATMENT OF ACUTE AND CHRONIC LIVER DISEASE AND SEVERAL MALABSORPTION SYNDROMES WITH MERCAPTOPROPIONYLGLYCINE, MPG (THIOLA).

(Ger.) Markoff, N. G. (Medizinische Klinik des Kantonsspitals, Loestrasse 135, CH-7000 Chur, Switzerland). *Praxis* 64(30):958-961; 1975.

Experiences in the management of acute and chronic liver disease with α-mercaptopropionylglycine (MPG) were compiled. MPG is absorbed rapidly by the gastrointestinal tract, with an equally rapid renal excretion. It is concentrated in the pancreas, liver, adrenals, and kidney. Up to 70% is found in RBC and up to 60% in the serum protein, 30 min postinjection. Liver deposits are mainly mitochondrial, and alcohol dehydrogenase activity is elevated. The immunoglobulin M level was significantly depressed, without demonstration of immunosuppression, in acute viral hepatitis patients after 15 days of MPG treatment. The transaminase levels were reduced, BSP retention and clearance were improved, and pretreatment biopsy was modified after daily doses of 2.5 g MPG in 80 patients with chronic persistent and chronic active hepatitis or compensated cirrhosis. Enzymatic normalization did not occur. In the long-term management of 50 patients with nonalcoholic chronic disease, side-effects did not appear, unlike D-penicillamine treatment; only slight differences over controls were established. MPG at doses of 1,000 mg/day, p.o., was without sequelae, but it had the same effect as 0.9 g/day of D-penicillamine in a 21-yr-old man with Wilson's disease. Urinary Cu rose from 370 to 420 μg/day and the urinary Cu reaction rose from 21 to 22 μg% in this patient. Combined MPG-penicillamine therapy had no effect on Cu metabolism in nine patients with Wilson's disease. Administration of MPG (5.5 g/day, i.v.) for 1-4 months led to complete normalization of the intestinal mucosa in several of 29 patients with malabsorption syndromes, including 10 with chronic active hepatitis.

8883 THE EFFECT OF RIFAMPICIN ON LIVER MORPHOLOGY IN TUBERCULOUS ALCOHOLICS. (Eng.)

Thompson, J. E. (New South Wales Health Commission, 86 George Street, Sydney, NSW, Australia). *Aust. N.Z. J. Med.* 6(2):111-116; 1976.

The livers of 79 tuberculous patients, including 36 alcoholics, who received rifampicin therapy, were examined to determine the relation of pre-existing changes in liver cell and lobule morphology to rifampicin therapy. Rifampicin (8 mg/kg/day) was administered in combination with isoniazid and another drug (either ethambutol or streptomycin). Six patients, five of whom were alcoholic, developed acute liver disease. Eleven patients had histological changes in their initial liver biopsies, ranging from fatty infiltration consistent with alcoholic liver disease to chronic active hepatitis. At 2 months, four patients showed histological changes not seen on initial biopsy, while fatty changes had either disappeared or greatly diminished in all patients in whom they were previously present. Some portal inflammation and patchy swelling of the liver cells were noted in three of the four, and an increase in severity of the changes of active chronic hepatitis occurred in the fourth. The fifth patient showed fatty changes on initial biopsy, accompanied by a slight rise in SGPT. At 1 month after initiation of treatment, he developed severe clinical liver disease and a deterioration of liver function tests. Patients with both normal pretreatment liver function tests and normal biopsies did not develop histological abnormalities. In one patient, chronic active hepatitis is believed to have followed irregularly taken rifampicin. It is suggested that alcoholics are particularly susceptible to idiosyncratic reactions of the liver, both clinical and subclinical, and that rifampicin is contraindicated in alcoholics with initial abnormal liver function tests.

8884 LIVER DISEASE IN DRUG ADDICTS: FREQUENCY EPIDEMIOLOGY AND SOCIAL IMPORTANCE. (Eng.)

Helmstaedt, D.; May, B. (Dept. Medicine, Medizinische Hochschule Hannover, D-3000 Hannover, Karl-Wiechert Allee 9, W. Germany). *Int. J. Clin. Pharmacol. Biopharm.* 12(1/2):46-49, 1975.

The incidence and epidemiology of liver disease among 257 drug addicts or persons in contact with drug addicts were evaluated. Of the 257 subjects, 189 had taken drugs i.v., 46 had taken drugs p.o., and 22 had taken no drugs, but had visited the addicts at a drug center. Thirty medical students served as controls. The bilirubin level was elevated in 15.1% of 35 addicts tested. Fifty-four percent of the 189 i.v. drug users had signs of liver disease. The frequency of similar pathological findings in the p.o. drug users was 10%; no hepatic abnormalities were seen in the controls. Viral etiology accounted for liver disease in 8.9% of the cases. Indications for chronic aggressive and persistent hepatitis were found in approximately 20% of the patients. The cases of liver disease in contact persons, as well as new infections within the therapeutic community, suggest that close contact with drug addicts favors the transmission of liver disease.

8885 OBLITERATIVE DISEASE OF LIVER VEINS: CLINICAL, DIAGNOSTIC, THERAPEUTIC AND PATHOGENETIC ASPECTS OF BUDD-CHIARI SYNDROME. (Ger.

Butzow, G. H.; Burkhardt, A.; Novak, D.; Becker, K. (I. Medizinische Klinik der Universitat, 2000 Hamburg 20, Martinistrasse 52, W. Germany). *Dtsch. Med. Wochenschr.* 101(9):329-334; 1976.

Three case reports of veno-occlusive disease in the liver are presented. A 32-yr-old man with a history of transient icterus and varicosities was found to have hepatosplenomegaly, ascites, and prominent presentation of veins on the lateral abdominal wall. Histologically, there was evidence of postnecrotic cirrhosis, and there was scintigraphic confirmation of a parenchymal defect. Cavography found the contrast medium to be arrested at the level of thoracic 12. Following death from liver coma, an autopsy showed subtotal caval occlusion from the diaphragmatic hiatus to the iliac veins. Especially at the diaphragm level, the vena cava was densely fibrous, with extensive thrombi. The main trunks of the hepatic veins were also extensively thrombosed, and the parenchyma showed partly confluent, partly centrilobular fibrosis. A 19-yr-old woman presented with lower limb edema, ascites, iliac and femoral vein occlusion, and caval narrowing at the level of thoracic 10-11, 3 weeks after the third pregnancy. Streptokinase and urokinase elicited generalized venous relief and revasculariza tion, with overall improvement. A 34-yr-old woman with a history of taking oral contraceptives presented with limb edema, hepatomegaly, lowered cholinesterase, hepatic vein occlusion, and caval narrowing. Liver biopsy showed sinusoidal ectasia, storage defect, and increased periportal stroma. Heparin, corticosteroids, saluretics, and aldosterone antagonists elicited only transient amelioration. At autopsy, the liver showed typical venous obliterative processes with stromal replacement, but without evidence of caval or hepatic trunk thrombosis. These cases illustrate the two mechanisms involved: thrombosis and obliterative devascularization (endophlebitis hepatica). The latter has two localizations, either the large hepatic veins, including the ostia, or the small sublobular and central veins or venules ("venoocclusive disease").

8886 IDENTIFICATION OF BILE ACIDS IN THE SERUM AND URINE IN CHOLESTASIS. EVIDENCE FOR 6 α-HYDROXYLATION OF BILE ACIDS IN MAN. (Eng.)

Summerfield, J. A.; Billing, B. H.; Shackleton, C. H. L. (Royal Free Hosp., Pont St., Hampstead, London NW3 2QG, England). *Biochem. J.* 154(2):507-516; 1976.

The bile acid pattern in large volumes of urine and plasma from two women with primary biliary cirrhosis was examined. The acids were subjected to a group separation and were identified by

mbined gas chromatography-mass spectrometry. The
chniques were developed to allow identification
the minor components of the bile acid mixture.
ur bile acids that have not been previously
scribed in human urine and plasma were detected:
,7α-dihydroxy-5β-cholan-24-oic acid; 3α,6α-
hydroxy-5β-cholan-24-oic acid (hyodeoxycholic
id); 3α,6α,7α-trihydroxy-5β-cholan-24-oic acid
yocholic acid); and 3α,7β,12α-trihydroxy-5β-
olan-24-oic acid. In addition, three C_{27} steroids
re found; 26-hydroxycholesterol and a trihydroxy
olestane, probably 5β-cholestane-3α,7α,26-triol,
re found in the sulfate fraction of plasma and
ine. In the plasma sample, a sulfate conjugate
24-hydroxycholesterol was found. These results
pport the hypothesis that there is an alternate
thway for bile acid metabolism in man, similar
that described in rats.

87 STUDIES IN CHOLESTASIS OF PREGNANCY: IV.
SERUM LIPIDS AND LIPOPROTEINS IN RELATION
DURATION OF SYMPTOMS AND SEVERITY OF THE DISEASE,
D FATTY ACID COMPOSITION OF LECITHIN IN RELATION
DURATION OF SYMPTOMS. (Eng.) Johnson, P.
ahlgren's Hosp., Univ. Goteborg, S-413 45 Gothen-
rg, Sweden). *Acta Obstet. Gynecol. Scand.* 54(4):
7-313; 1975.

matological data and information on serum lipids,
poproteins, and lecithin fatty acids were obtained
39 pregnant women with cholestasis of pregnancy
trace possible variations in the influence of
egnancy and cholestasis on liver metabolism.
ven patients had pruritus gravidum (PG) of short
ration, 11 had PG of long duration, 12 had hepa-
sis of pregnancy (HP) of short duration, and 9
d HP of long duration. Twenty women with uncom-
icated pregnancies served as controls. The mean
rum cholesterol level in the patients with HP of
ort duration (351 mg/100 ml) was significantly
gher than that in the controls (265 mg/100 ml).
e mean serum triglyceride level in the patients
th HP of short and long duration (278 and 250 mg/
0 ml, resp.) was significantly greater than that
the controls (180 mg/100 ml). In the patients
th HP of short duration, the mean serum phospho-
pid level (386 mg/100 ml) was significantly
gher than that in controls (283 mg/100 ml). The
gh density lipoprotein cholesterol level was
gnificantly lower in the patients with HP of long
ration (50 mg/100 ml) than of that in the controls
7 mg/100 ml). The low density lipoprotein chole-
erol level in the patients with HP of short dura-
on was significantly higher (212 mg/100 ml) than
at in controls (147 mg/100 ml). Serum iron was ele-
ted by 55% in HP of short duration. The palmitic
id level was significantly lower in CP of short
ration and even lower in CP of long duration. The
achidonic acid level was significantly higher in CP
short duration, while linoleic acid was signifi-
ntly lower. The molar ratio of linoleic to arachid-
ic acid was low (3.0) after CP of short duration
d high (4.9) after CP of long duration. The
sults support the hypothesis of an abnormal
action of liver metabolism to estrogens in the
itial stage of cholestasis of pregnancy.

8888 THE BILE SECRETORY FUNCTION OF THE HEPATOBILIARY SYSTEM DURING PREGNANCY. (Rus.) Vinogradova, M. R. (Inst. Obstetrics Gynecology, USSR Acad. Medical Sciences, Leningrad, USSR). *Akush. Ginekol. (Mosk.)* (7):38-42; 1975.

The bile secretory function of the hepatobiliary system was studied in 24 pregnant women presenting with dyspeptic symptoms or pains in the right hypochondrium. The investigation was performed by 5-min fractional examination after administration of a magnesium sulfate solution. The total bilirubin, cholesterol, and free fatty acid concentrations in the bile showed marked variation from one phase to the next, being highest during phase IV (B bile). The concentrating ability of the gallbladder increased with the advancement of the pregnancy, which accounted for the enteral release of considerable quantities of bile pigments, cholesterol, and free fatty acids. The findings suggest that a considerable portion of the bilirubin secreted by the liver in the advanced stages of pregnancy is in free form in the duodenal content. The tendency to spasm and increased tonus of Oddi's sphincter, observed during the first half of pregnancy, was followed by a tendency to retarded gallbladder evacuation during the second half.

8889 HYPOTHESIS: A MOLECULAR BASIS FOR THE HYPERAMMONEMIA AND POTASSIUM WASTAGE ASSOCIATED WITH HEPATIC FAILURE. (Eng.) .Zweig, J. I. (Beth Israel Medical Center, 10 Nathan D. Perlman Place, New York, NY 10003). *Mt. Sinai J. Med.* 43 (2):109-121; 1976.

A study was undertaken to determine if there was an association between blood ammonia and the dibasic amino acids during hepatic failure. Twenty patients in hepatic coma, 14 with liver disease and 6 without liver disease (controls), were studied. Among the patients with liver disease, the highest plasma lysine values occurred in those with an elevated venous ammonia. Of those with a venous blood ammonia above 200 mg/dl, none had a plasma lysine less than 24 µmol/dl. In the three patients who had arterial blood ammonia determinations >200 µg/dl, plasma lysine was ≤21 µmol/dl. In five of seven of the samples with elevated blood ammonia, plasma ornithine was also elevated. No conclusions were drawn regarding the effect on serum potassium or the blood urea nitrogen. In the control group, plasma lysine was ≤18 µmol/dl, and the plasma ornithine was <13 µmol/dl in four patients and 14 µmol/dl in one. This increase in lysine may be secondary to a decrease in its degradation by the liver and it may be the primary cause for the decreased urea production and increased ammonia formation via allosteric enzyme inhibition during hepatic failure. The potassium loss, also associated with liver failures, is explained on the basis of an intracellular surrogate ion effect of potassium that lysine appears to have. This mechanism may also be applicable in the case of ornithine, which bears a structural resemblance to lysine.

8890 FULMINANT LIVER FAILURE: CLINICAL AND EXPERIMENTAL STUDY.

(Eng.) Slapak, M. (Dept. Surgery, Univ. Cambridge, Cambridge, England). *Ann. R. Coll. Surg. Engl.* 57(5):234-247; 1975.

Clinical experience with some newer methods of hepatic support is presented, and an animal model based on carefully imposed ischemic hepatic insult in the absence of portacaval shunting is described. Among 21 patients in stage IV hepatic coma treated by exchange transfusion, 16 recovered consciousness, but only 4 survived. Exchange transfusion is costly, as it requires some 18 l of blood. Five of seven patients in stage IV hepatic coma regained consciousness during *ex vivo* perfusion, but none survived. Two patients were treated by cross circulation. The patient who received human-to-human cross circulation regained consciousness, but died of a hemorrhaging ischiorectal abscess, and the patient in whom a baboon was used as a cross-circulant never regained consciousness, despite a fall in prothrombin time from 60 to 18 sec. A previously described rat model in which the need for a portacaval shunt was eliminated is described. Because there were similarities in the hemodynamic disturbances found in this model and those found in septic shock, an experiment was devised to study the effect of reduction of alimentary bacterial content. In control rats that underwent colectomy, the mortality rate was 10%. Ninety minutes of hepatic ischemia in intact rats increased the mortality rate to 94%. However, if nonabsorbable kanamycin (1 mg/g) was given 2 days before operation and 2 days afterwards, the mortality was reduced to 21%. When bacterial reduction was accomplished by performing a colectomy, the mortality was 30%. In further experiments, the importance of portal flow on liver function and growth was assessed in hemihepatectomized dogs in which the remaining half of the liver was vascularized by the hepatic artery alone or in which portarenal transposition was performed. The latter procedure substituted renal venous blood and hepatic arterial blood for portal blood. Animals with hepatic arterial inflow only lost weight, had meat intoxication, and were hard to keep alive, even at 4 weeks; regeneration was only 14%. The course of the portarenal transposition, however, was entirely benign, and one animal has normal liver function 6 yr after the procedure. The authors concluded that if a specific regenerative factor was present in the portal blood, it required a minimal blood flow to the liver to be operative and that hepatic arterial blood flow was less than this minimum and was insufficient for normal hepatic regeneration. In a third series of experiments in dogs, it was concluded that liver grafts might be expected to be temporarily life-supporting in the absence of portal blood, in a heterotopic situation, and in the presence of an orthotopic liver.

8891 FOCAL NODULAR HYPERPLASIA OF THE LIVER AND INTRAHEPATIC HEMORRHAGE IN YOUNG WOMEN ON ORAL CONTRACEPTIVES.

(Eng.) Stauffer, J. Q.; Lapinski, M. W.; Honold, D. J.; Myers, J. K. (Dept. Medicine, State Univ. Hosp., 750 E. Adams St., Syracuse, NY 13210). *Ann. Intern. Med.* 83(3):301-306; 1975.

The cases of three young women (25-29 yr) on oral contraceptives in whom focal nodular hyperplasia o the liver was diagnosed are presented. The patien had taken oral contraceptives, including combinati of norethindrone plus mestranol and ethynodiolacet plus mestranol, for 6-7 yr. Patient 1 was gravida 1, para 1, while the other patients had never been pregnant. The first two patients presented with minimal clinical symptoms and a palpable mobile ma which was misdiagnosed as either an ovarian or mesenteric cyst. In patient 1, a single, 10-cm pedunculated mass arising from the left liver lobe was found and resected at surgery. The mass was highly vascular, but bleeding was controlled by ligatures at the base of the stalk. In patient 2, there were five areas of nodular hyperplasia, with central ischemic necrosis of the largest nodule and hemorrhagic necrosis in one of the smaller nodules. In both patients, the hepatocytes were altered, with vacuolated to clear cytoplasm and no evidence of nuclear atypia. There was a loss of a normal lobular pattern and absence of the normal plates of hepatocytes. In some areas there was a pseudorosette pattern. None of the specimens had fibrous tracts coalescing in the center of the lesions. There was no evidence of metastatic disease in either patient. Patient 3 presented wi massive intrahepatic hemorrhage, and, although no nodules were identified, the authors suspect that this represented a variant of the syndrome. They suspect that the intrahepatic hemorrhage in this patient was related to necrosis of a small nodule, with subsequent massive intrahepatic hemorrhage such that the area of nodular hyperplasia could no longer be recognized grossly. This patient surviv the hemorrhage, probably because it occurred in th lateral aspect of the right lobe, with compression of the bleeding area by the chest wall. This unus case was included in the series to stress that massive intranepatic hemorrhage may occur in young women who are on oral contraceptives, and that foc nodular hyperplasia may not be readily apparent at exploration. No patient has had recurrent nodule formation, but oral contraceptive use has not been reinstituted. The increased incidence of focal nodular hyperplasia of the liver in young women suggests a possible etiologic relation to long-ter contraceptive use.

8892 PATHOGENESIS OF PROTRACTED AND CHRONIC FORMS OF CHOLANGIOLITIC HEPATITIS.

(Rus. Bychkova, V. I. (Dnepropetrovsk Medical Inst., Dnepropetrovsk, USSR). *Ter. Arkh.* 48(3):71-73; 1976.

The pathological anatomy of protracted and chronic cholangiolitic hepatitis was studied in 23 patients in whom diagnostic laparotomy was performed after unsuccessful long-term drug therapy. Moderately enlarged, dense liver of green color was found in all patients. Lesion of all extrahepatic bile duct was observed in one patient; lesion of the common bile duct, especially of the distal portion, in six lesion of the common bile duct and of one hepatic or cystic duct in five; lesion of the common bile duct and of the gallbladder in three; and perichola gitis and pericholecystitis in four. The walls of ducts and of the gallbladder were thickened and dened, and their lumina were stenosed or sometimes iterated. Lympho-histiocytic infiltration of the ls of the ducts and of the gallbladder and proliftion of the connective tissue in the submucosa subserosa were observed. Distention of the galldder and of the common bile duct was observed in ee cases. Enlargement and hardening of the head the pancreas were observed in 11 cases. The lapaomy and the biochemical findings (hyperlipemia h predominant hypertriglyceridemia) indicate that erosis and stenosis of the distal portions of the e ducts are one of the causes of chronic and procted cholangiolitic hepatitis.

3 IMMUNOLOGICAL PARAMETERS, VIRAL ANTIBODIES, AND BIOCHEMICAL AND HISTOLOGICAL FINDINGS RELATIVES OF PATIENTS WITH CHRONIC ACTIVE HEPAIS AND PRIMARY BILIARY CIRRHOSIS. (Eng.) Salaso, M. P.; Laitinen, O. I.; Lehtola, J.; Makkonen, Rasanen, J. A.; Sipponen, P. (Second Dept. Medie, Univ. Helsinki, 00290 Helsinki 29, Finland). *nd. J. Gastroenterol.* 11(3):313-320; 1976.

ety-seven first-degree relatives of 23 propositi h either typical chronic active hepatitis (CAH, or primary biliary cirrhosis (PBC, 10) were examd for different viral and tissue antibodies, immulobulins (Ig), and biochemical parameters. Signiantly higher prevalences of tissue antibodies were ed mostly in the relatives of the CAH patients. ormalities in Ig levels were frequently found in h groups, but no difference in Ig or complement els was noted between the groups. Instead, there a marked clustering of abnormalities in some ilies. The age of the relatives and the patholcal Ig values were not related. Very high antiy titers to measles and rubella occurred only in atives of the CAH patients, and even then the h titers were clustered in only three families. y when relatives had biochemical abnormalities a liver biopsy performed. Unspecific inflammay changes were noted in five relatives of CAH ients and in four relatives of PBC patients. two relatives of PBC patients and in one relative CAH patients, active liver disease was detected. ked accumulation of various immunological and topathological abnormalities was noted in four ilies. The results of this study support the othesis of a genetic predisposition for the elopment of either CAH or PBC.

4 GLYCOGENIC FUNCTION OF THE LIVER IN PATIENTS WITH ICHTHYOSIS. (Rus.) Kuklin, V. T.; tsov, V. K.; Belinskaia, R. G.; Velichanskaia, B. (Dept. Skin and Venereal Diseases, Irkutsk ical Inst., Irkutsk, USSR). *Vestn. Dermatol. erol.* (2):56-59; 1976.

od sugar curves were determined after administran of 100 g of glucose in 43 patients with xeroma, in 18 patients with nacreous form of ichosis vulgaris, and in 9 patients with ichthyosiform erythroderma. The patients included both children and adults. The blood sugar curves were normal in 26 cases (15 cases of xeroderma, 6 cases of nacreous ichthyosis, and 5 cases of ichthyosiform erythroderma); torpid (with 30% hyperglycemia in 30-60 min) in 29 (17 cases of xeroderma, 10 cases of nacreous ichthyosis, and 2 cases of ichthyosiform erythroderma), irritative (rapidly rising and falling) in 1 patient each with xeroderma and nacreous ichthyosis, and paradoxical (declining during the first 30-60 min) in 1 patient each with xeroderma and nacreous ichthyosis. The blood sugar curve showed no definite pattern in 11 cases. The high incidence of torpid blood sugar curves and their normalization in 2 hr indicate the reduced excitability of the sympathetic nervous system and suggest the decrease of the oxidative processes in the hepatocytes and reduced hepatic glucokinase activity. The increased neutral mucopolysaccharide level in the horny layer appears to be linked to the reduced assimilation of glycogen by the epidermal cells. The findings indicate no impairment of the functional activity of the islands of Langerhans in ichthyosis.

8895 HEPATOCYTE ENZYME INDUCTION BY PHENOBARBITAL: APPLICATIONS IN THE THERAPY OF JAUNDICE. (Fre.) Nusinovici, V.; Darnis, F.; Levy, V. G.; Coroli, J. (Hopital Saint-Antoine, 184, rue du fg Saint-Antoine, 75012 Paris, France). *Sem. Hop. Paris Ther.* 52(3):171-174; 1976.

Phenobarbital (PB)-induced liver enzyme induction and its role in icterus therapy are reviewed. Regression of the pruritus was achieved in four hypercholestatic hepatitis patients, with a near total disappearance of the interlobular bile ducts; cholestyramine was ineffective. Icterus is more refractory to PB than pruritis. At best, PB can induce a moderate decrease in bilirubinemia. In two of four of the cholestatic hepatitis patients, a decrease followed by a significant increase in bilirubinemia occurred after PB interruption. The pruritis regresses due to reduction of the plasma bile acid level. There was a reduction in both total lipids and total cholesterol, triglycerides, and phospholipids from 40-60 to 20 g/l in 2-3 months in these four patients. Infants tolerate 3-12 cg PB without difficulty. The daily adult dose is usually 15-25 cg; doses >30 cg induce arthralgias after several weeks. Osteomalacia and acute intermittent porphyria are rare complications. Chronic congenital icterus with nonconjugated bilirubin is probably due to a deficit in glucuronyl transferase or protein Y activity. PB doses of 6-18 cg/day in some cases reduce the bilirubinemia to near normal levels. Maternal administration of PB just prior to parturition significantly suppresses the intensity of neonatal icterus. Dicophane and ethyl alcohol elicit similar effects. PB has been used routinely in intrahepatic cholestases, including primary biliary cirrhosis, cholestatic hepatitis, and pediatric atresia of the intrahepatic bile ducts; and glutethimide may also be used. PB modifies icterus, bile acid metabolism, and any concomitant pruritis, hyperlipemia, and xanthomatosis.

8896 CHOLESTATIC JAUNDICE. (Eng.) Javitt, N. B. (New York Hosp.-Cornell Medical Center, New York, NY 10021). *Med. Clin. North Am.* 59(4): 817-821; 1975.

A review and discussion of information concerning cholestatic jaundice is presented. Cholestasis is best detected by an increase in serum bile acid concentration and is a feature of most, if not all, diseases of the liver and biliary tract. In both anicteric A or B viral hepatitis and in chronic active hepatitis, serum bile acid levels are elevated. In the former case, the level is a sensitive indicator of recovery from the disease, and in the latter case, the degree of elevation appears related to the severity of the illness. Although sufficient data have not been accumulated on the relative merit of using serum bile acid in the evaluation of biliary tract disease, a knowledge of the serum bile acid concentration is necessary if the disease is managed by the administration of bile acid preparations. The only other indicator of the presence of cryptogenic cholestasis, in addition to elevated bile acid levels, is the presence of pruritus. Because there is no associated defect in bilirubin excretion in neonatal cholestatic syndromes, patients develop conjugated hyperbilirubinemia only when the cholestasis is most severe and there is no bile flow. The only known treatment for this disease is the reduction of the bile salt load on the liver by the use of anion-exchange resins, such as cholestyramine, to prevent the reabsorption of bile acids from the intestine. This treatment is also effective in primary biliary cirrhosis. The two prominent features of primary biliary cirrhosis occurring early in its course and before cirrhosis are: an inflammatory reaction in the portal areas, with bile ductules as the apparent target with necrosis of biliary epithelium, and severe cholestasis associated with pruritus. Patients with primary biliary cirrhosis must be warned not to take medications other than those used in the treatment of the disease, as many drugs are at least partly metabolized and excreted in bile.

8897 EXTRAHEPATIC PORTAL HYPERTENSION AND PREGNANCY. (Ger.) Huchzermeyer, H. (Abteilung fur Gastroenterologie und Hepatologie, Department Innere Medizin der Medizinischen Hochschule Hannover, Karl-Wiechert-Allee 9, D-3000 Hannover, W. Germany). *Leber Magen Darm* 5(5):209-213; 1975.

The interrelation between pregnancy and portal hypertension was analyzed in patients with prehepatic block. The clinical sample included six patients. All cases had protracted histories of bleeding from esophageal varices. A mesentericocaval anastomosis was ineffective in one patient, and an unexceptional pregnancy was interrupted in the fourth month; the bleeding did not resume. Another pregnancy was interrupted in a patient with splenorenal anastomosis. A third patient, in whom anastomoses were technically not possible, succumbed from a recurrent mediastinitis during the first trimester. A fourth case, with splenectomy and splenorenal anastomosis after portal thrombosis and melena, had a complication-free pregnancy and a healthy baby. A fifth patient present with a history of splenomegaly and hematemesis. Splenectomy followed a suspicion of splenic vein thrombosis. A mesentericocaval anastomosis was no possible because of a cavernous transformation of the portal vein and superior mesenteric artery and portal pressure of 30 cm H_2O. There was no eviden of cirrhosis. Melena preceeded a complication-fre pregnancy and a healthy baby. The sixth patient h a successful first pregnancy after splenectomy for hematemesis, but massive intestinal bleeding occur during a second pregnancy. Icterus developed seco ary to post-transfusion hepatitis. Postpartum fun tion tests found elevated transaminases, hypalbumi mia, and hypergammaglobulinemia. Active chronic hepatitis was discovered during a third pregnancy, with icteric episodes and decompensated cirrhosis. Since portal hypertension is a physiological rule in pregnancy, pathological hypertension is exacerbated. The physiological changes of the circulato system during pregnancy may be responsible for the observed complications; i.e., temporary increases portal pressure tend to aggravate the preexisting extrahepatic portal hypertension.

8898 FATTY LIVER: BIOCHEMICAL AND CLINICAL CONSIDERATIONS. (Eng.) Hoyumpa, A. M., Jr.; Greene, H. L.; Dunn, G. D.; Schenker, S. (Vanderbilt Univ. Medical Sch., Nashville, TN 37203). *Am. J. Dig. Dis.* 20(12):1142-1170; 1975.

The main clinical and biochemical features of the principal conditions associated with fatty liver a reviewed. Normal hepatic lipid metabolism and ethanol-induced fatty liver, kwashiorkor, obesity and intestinal bypass, diabetes, idiopathic fatty liver of pregnancy, Reye's syndrome, and inherited metabolic disorders are discussed. The induction of fatty liver by tetracyclines and other drugs is also discussed. Steatosis is a common and nonspec response of the liver to different forms of acquir injury or inherited metabolic derangement. Fatty liver can be acute and fulminating, as in fatty li of pregnancy and Reye's syndrome, or insidious and benign, as in the fatty liver of obesity and diabe Its presence is best detected by histological exam tion, and the differential diagnosis is aided by noting the fat distribution in the hepatic lobule and the location of the nucleus in the hepatocyte. In the more common types of fatty liver (alcoholic kwashiorkor, obesity, post-jejunoileal bypass, and diabetes), the cytoplasm of the hepatocyte is distended by large fat globules that displace the nucleus peripherally. Fine intracellular fat vacuole that do not displace the nucleus suggest idiopathi fatty liver of pregnancy, tetracycline toxicity, Reye's syndrome, or cholesterol ester storage disease. Moreover, a centrilobular fat distribution suggests idiopathic fatty liver of pregnancy, rath than tetracycline toxicity or Reye's syndrome. In very severe cases, differentiation based on lobula fat distribution can be obscured; for example, the usual periportal fatty change in kwashiorkor and the centrolobular fat distribution in obesity both become diffuse in the severe forms of these disord Further investigation of the different steps in th ansport, uptake, formation, and secretion of lipids the liver is needed, and these functions must be elated to the different structures and functions the hepatocyte organelles, both under normal and onormal conditions.

399 EARLY DIAGNOSIS OF HEPATOLENTICULAR DEGENERATION IN CHILDREN.

(Rus.) Bondarchuk, A. .; Vakharlovskii, V. G.; Kliorin, A. I.; Meliucheva, . A.; Shavlovskii, M. M.; Iakovnika, E. O.; Neifakh, . A. (Inst. Experimental Medicine, USSR Acad. Medical ciences, Leningrad, USSR). *Vopr. Okhr. Materin. Det.*)(12):28-33; 1975.

eventy case histories, including 18 new cases, of epatolenticular degeneration were analyzed with espect to the possibilities of early diagnosis. isceral symptoms (jaundice, hepatomegaly, hepatoplenomegaly, arthralgia, hemorrhagic symptoms, and emolytic episodes) were the first manifestation f the disease in 48 cases. These symptoms usually ppeared at the age of 10-12 yr. Changes in the EG were already found in some patients during the isceral stage of the disease. The preclinical tage of hepatolenticular degeneration was diagnosed n 1 of 29 children examined for suspected chronic epatitis by the serum ceruloplasmin test and other iochemical tests. The same stage of hepatolenticlar degeneration was diagnosed in two siblings. he findings indicate that in the presence of visceral ymptoms, the early diagnosis of hepatolenticular egeneration is possible by the serum ceruloplasmin est; to confirm the diagnosis, the determination f the 24-hr copper and amino acid excretion in the rine, the determination of copper in liver biopsy amples, and an EEG should be performed. The eyes hould be examined through slit lamp for Kayserischer rings. Treatment initiated before the anifestation of neurological symptoms can prevent heir development.

900 HEPATIC ZONAL DEGENERATION AND NECROSIS IN REYE SYNDROME.

(Eng.) Brown, R. E.; Isak, K. G. (J. C. Blair Memorial Hosp., Huntingdon, A). *Arch. Pathol. Lab. Med.* 100(3):123-126; 1976.

he clinicopathological features in seven children ith Reye's syndrome associated with considerable epatic zonal degeneration and/or necrosis are preented. The primary findings in these cases fit into the clinicopathological spectrum of Reye's synrome. All patients had antecedent febrile or viral ype of illness, followed by vomiting, encephaloathy, and death. Cerebral edema occurred in five atients. Small-droplet fatty accumulation was een in the viscera at autopsy in six cases. Only wo patients were jaundiced, and there was only a ild to moderate elevation in total serum bilirubin 1.9-4.4 mg/100 ml) in the four patients in whom his was measured. None of the patients had a istory of exposure to toxins, including phosphorus. eripheral zonal degeneration without necrosis was evealed in liver sections from two patients, characerized by distinctive ballooning. Peripheral onal necrosis without ballooning was present in three cases. Peripheral zonal degeneration and hemorrhagic necrosis were present together in two patients. Cytoplasmic cholestasis occurred in six cases, canalicular cholestasis in three, and acute cholangiolitis in three. The authors hypothesize that fatty acids are the agents most likely to be responsible for the pathogenesis of the peripheral zonal alterations in these patients.

8901 VINYL CHLORIDE-ASSOCIATED LIVER DISEASE.

(Eng.) Berk, P. D.; Martin, J. F.; Young, R.; Creech, J.; Selikoff, I. J.; Falk, H.; Watanabe, P.; Popper, H.; Thomas, L. (Section on Diseases of the Liver, Digestive Diseases Branch, Natl. Inst. Arthritis, Metabolism and Digestive Diseases, Building 10, Room 4D-52, NIH, Bethesda, MD 20014). *Ann. Intern. Med.* 84(6):717-731; 1976.

Two cases of vinyl chloride-associated liver injury, one hepatic fibrosis and one angiosarcoma, that occurred in two men are presented. The fibrosis occurred in a 30-yr-old vinyl chloride polymerization worker who, for the first 5.5 yr of his 8-yr career, was involved in cleaning the polymerization tanks, an operation associated with high exposure. His case demonstrated that vinyl chloride-associated hepatic fibrosis persists after removal from further exposure and that the lesions may be extensive even though standard liver function tests have normal findings. The angiosarcoma occurred in a 42-yr-old man who had been doing the same task for 2 yr. In each patient, the histologic features were similar to the hepatic fibroses and angiosarcomas associated with chronic exposure to inorganic arsenicals. It is suggested that the toxicity of vinyl chloride may result from the formation, during high-dose exposure, of active metabolites by mixed function oxidases of the liver.

8902 THE EFFECT OF LONG TERM TREATMENT WITH PENICILLAMINE ON THE COPPER CONTENT IN THE LIVER IN PATIENTS WITH WILSON'S DISEASE.

(Eng.) Marecek, Z.; Heyrovsky, A.; Volek, V. (I. Medizinische Klinik der Karls-Universitat, 128 08 Prague Unemocnice 2, Czechoslovakia). *Acta Hepatogastroenterol.* 22(5):292-296; 1975.

The effect of long-term treatment with penicillamine on the hepatic copper content was studied in 35 biopsy specimens of 17 patients with Wilson's disease. At the time of the study, the patients' urinary Cu levels ranged between 76 and 889 μg/24 hr, and the serum Cu levels ranged between 21 and 73 μg/100 ml. The pretreatment hepatic copper levels among nine patients ranged between 682 and 1,520 μg/g dry liver. In six patients treated with penicillamine (1,000-1,500 mg/day) for 1-2 yr, the liver Cu concentrations ranged between 570 and 860 μg/g dry liver. In five patients treated for 3-4 yr, the levels were between 389 and 688 μg/g dry liver; in five patients treated for 5-7 yr, 288-356 μg/g; in one patient treated for 8-10 yr, 208 μg/g; and in one patient treated for 11 yr, 139 μg/g. When the mean hepatic Cu levels were plotted against years of treatment, it was shown that during the course of treatment, the Cu content decreased gradually and very slowly reached the normal level (250 μg/g dry liver). There was a significant positive correlation between urinary and hepatic Cu concentrations, both before and during treatment. Thus, the urinary Cu content is a good indirect indicator of hepatic copper concentration.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

8944 EXPERIENCE WITH THE PHOTOTHERAPY OF NEWBORN INFANTS. (Ger.) Mucke, J.; Raue, W.; Klossek, D.; Kothe, Ch.; Winiecki, P. (Kinderklinik des Bereichs Medizin der Karl-Marx-Universitat, 705 Leipzig, Oststr. 21-25, E. Germany). *Dtsch. Gesundheitswes.* 31(1):38-42; 1975.

The results of phototherapy in neonatal metabolic hyperbilirubinemia are reported. The clinical sample included 900 infants with serum bilirubin in excess of 14 mg%. Approximately 70 cm of skin surface was exposed; the radiation strength was equivalent to 0.7 milliwatts/cm^2 and was administered until unequivocal serum bilirubin depression. Enzyme induction by phenobarbital (10 mg/kg/day x 2) occurred on postnatal days 1-3. Significant serum bilirubin decreases were achieved by postnatal days 5-7 in neonates with birth weights above 2,500 g, compared to those in neonates with birth weights below 2,500 g ($p=0.01$). By day 4, neonates receiving both phototherapy and enzyme induction had significantly lower serum bilirubin ($p=0.05$) than the group receiving phototherapy only, independent of birth weight. Transfusions did not affect the phototherapy result. Phototherapy sequelae included a 0.5-1.5 C hypothermia without generalized distress in 87 cases; respiratory frequency was increased in 35 cases. Phototherapy in Rh and ABO incompatibility is recommended.

8945 EFFECT OF PHOTOTHERAPY ON HEPATIC EXCRETORY FUNCTION IN NEWBORNS AS MEASURED BY
BROMSULPHALEIN CLEARANCE. (Eng.) Rubaltelli, F.
F.; Donzelli, F.; Largajolli, G. (Dept. Pediatrics
Univ. Padua, I-35100 Padua, Italy). *Biol. Neonate*
26(5/6):333-336; 1975.

To determine whether the excretion of unconjugated
bilirubin is mediated by an enhanced general
biliary excretion of other biliary components, the
clearance of BSP was studied in 12 jaundiced newborns both before and after phototherapy. The
mean unconjugated bilirubin level was 12 mg/100 ml
The BSP clearance graph showed that the percentage
of BSP disappearance was not significantly different before and after phototherapy. The results ar
consistent with the hypothesis that phototherapy
causes the photodegradation of bilirubin and that
the increased excretion of unconjugated bilirubin
is not mediated by a generalized enhancement of
the hepatic output.

8946 BILIRUBIN REMOVAL BY ANION-EXCHANGE RESI
(Eng.) Lopukhin, U. M.; Shurkalin, B. K.
Leykin, U. A.; Evseev, N. G.; Molodenkov, M. N.; K
netzov, V. N.; Gorchakov, V. D.; Blagosklonov, A.
(2nd Moscow Medical Inst., Malaya Pirogovskaya 1A,

oscow, USSR). *Lancet* 2(7932):461; 1975.

n anion-exchange resin was used to remove bilirubin rom a jaundiced patient. The patient, a 71-yr-old n, had an enlarged gallbladder and a solid liver argin with several palpable swellings. The SGOT, PT, and serum total bilirubin were 70 mU/ml, 50 mU/ l, and 12.9 mg/dl (direct 8.7), resp. Conventional onservative treatment (including glucose infusions, ntibiotics, and corticosteroids) was ineffective. emosorption was undertaken. After heparin infusion, e patient's blood was perfused through a polyethylacrylate column filled with 70 g of the anion- xchange resin MCTI-2A for 30 min. The arterial d central venous pressures, hematocrit, and acid- ase balance did not change. The platelet count ell by 10-12%, but the WBC count did not change. e total bilirubin fell by a third, from 15.6 to .5 mg/dl (14.0-7.5 direct). The electrolyte, urea, d glucose levels did not change. The total pro- ein fell from 6.2 to 5.3 g/dl, and the calcium oncentration fell from 7.7 to 6.0 mg/dl. The next ay, the patient's condition was improved, and the otal bilirubin was 13.8 mg/dl (direct 6.6). ollowing removal of a large tumor of the ampulla f Vater, the total bilirubin was 7.9 mg/dl (direct .2). The results suggest that it is possible to emove bilirubin from the blood of patients with bstructive jaundice, using hemosorption on blood- ompatible anion-exchange resin.

947 CHRONIC HYPERBILIRUBINEMIA ASSOCIATED WITH HEPATIC UPTAKE AND STORAGE IMPAIRMENT. A EW SYNDROME RESEMBLING THAT OF THE MUTANT SOUTHDOWN HEEP.

(Eng.) Dhumeaux, D.; Berthelot, P. (Dept. 'Hepatogastroenterologie, Hopital Henri Mondor, 4010 Creteil, France). *Gastroenterology* 69(4):988- 93; 1975.

case of chronic benign hyperbilirubinemia associ- ted with a marked impairment of hepatic uptake and torage of cholephilic organic anions is presented. he patient, a 19-yr-old woman, had a 10-yr history f chronic jaundice. She presented with slight left ypochondrium pain, moderate asthenia, and chronic arkening of the urine. The extreme values for serum otal bilirubin were 2.9 and 5.2 mg/100 ml, but all ther hepatic function tests were normal. Opacification of a normal gallbladder followed p.o. administra- ion of iopanoic acid (6 g), but only after a 20-hr elay. A 5-hr infusion of methylglumine adipiodone (15 g) failed to visualize the bile ducts. Hepatic ilirubin uridine diphosphate-glucuronyl transferase activity was normal. The serum bile acid concentra- tion was less than 1 μg/ml. The BSP plasma disappear- ance rate (K_1) was markedly reduced (0.050; normal, .145), and there was no plasma secondary rise of the dye. Eight percent of BSP found in the plasma 40 min after an i.v. injection of 5 mg/kg was conjugated. BSP urinary excretion was about 5% of the dose adminis- tered; 52% of the dye in the urine was conjugated. Following the i.v. injection of 4 mg/kg dibromosulfophthalein, 5 mg/kg rose bengal, or 0.5 mg/kg indocyanine green, the K_1 values were 0.021 (normal, 0.234), 0.026 (normal, 0.077), and 0.028 (normal, 0.185), resp. The relative storage capacity (*S*) for BSP was markedly reduced (20.0 mg/100 ml; normal, 67.7 mg/100 ml). *S* for dibromosulfophthalein was decreased (31.1 mg/ 100 ml; normal, 124.6 mg/100 ml), as was the biliary transport maximum (*Tm*) for both dibromosulfophthalein (4.4 mg/min) and BSP (5.7 mg/min). The percentage of the infused dose excreted in the urine during the *Tm* and *S* tests was about 8% for BSP and 11% for dibromosulfophthalein; 25% of BSP in the urine was conjugated. Phenobarbital (100 mg/day, 15 days) administration did not modify either serum bilirubin or BSP K_1. This new form of chronic benign hyperbilirubinemia seems to be primarily due to a defect of hepatic uptake and storage, and closely resembles the disease observed in mutant Southdown sheep.

8948 OCCURRENCE OF BENIGN CONJUGATED HYPERBILIRUBINEMIA WITH PIGMENT IN THE LIVER (DUBIN-JOHNSON'S SYNDROME). PART I.

(Slo.) Sosovec, V.; Ivicic, L.; Gaspar, I.; L'Achova, B. (Vnutorne oddelenie, Nemocnica s poliklinikou, Levoca, Czechoslovakia). *Cesk. Gastroenterol. Vyz.* 29(6):400-405; 1975.

The nature of Dubin-Johnson syndrome (DJS) and its clinical manifestations are reviewed, and 11 cases in four Gypsy families are described. Patients included a 3-week-old infant (possibly the youngest individual with diagnosed DJS), six children aged 6-14 yr, and four adults aged 18-78 yr. Liver enlargement was observed in seven cases. The serum level of total bilirubin varied between 1.9 and 6.6 mg% (with the exception of the infant, in whom icterus neonatorum gravis was suspected), while that of conjugated bilirubin varied from 0.4 to 4.5 mg%. Bilirubin was present in the urine in all but two cases, serum glutamate-pyruvate transaminase levels were within the normal range in all patients, and alkaline phosphatase levels were clearly elevated in five cases. Of the seven cases in which i.v. cholecystography was performed, the filling of the gallbladder with contrast medium took 3-7 hr in two cases and 15-17 hr in another two, continuing even after 24 hr. Thus, the absence of gallbladder filling cannot be considered a diagnostic criterion. The BSP test revealed two peaks (retention in the blood was less after 45 min than after 210 min) in all the patients, indicating its diagnostic value; liver biopsy confirmed the diagnosis in all nine cases in which it was performed. The serum cholesterol level varied over a wide range, but was clearly high in all the adults, while no essential deviations in prothrombin time were observed. Three cases could be considered to have progressed asymptomatically. Although no kinship ties among the four families studied were established, the possibility cannot be excluded, since Gypsies live in isolated groups. The father of one family had married his mother's cousin, by whom he had eight children, four of them DJS patients. This is not necessarily sufficient proof of genetic carriership of DJS, however.

8949 NEONATAL JAUNDICE AS A CAUSE OF DEAFNESS.

(Eng.) Fenwick, J. D. (Queen Elizabeth Hosp., Edgbaston, Birmingham 15, England). *J. Laryngol. Otol.* 89(9):925-932; 1975.

The clinical findings in 18 children in whom deafness was related to a period of neonatal jaundice are presented. There were 16 boys and 2 girls. The jaundice was due to Rh incompatability in 16 cases and to ABO incompatability in 1 case; in the remaining patient, deafness followed the occurrence of maternal jaundice of unknown etiology 2 days before the onset of labor. Ten patients had a sudden hearing loss at 1,000 cycles per second (cps). Three cases had a U-shaped curve on the audiogram (hearing loss in decibels plotted against cps), with a maximal loss at 2,000 cps and some recovery at very high tones. Two patients had a flat audiogram, and the remaining three patients were so mentally backward that thresholds could only be obtained with evoked response audiometry. A mean audiogram was produced by averaging the hearing thresholds at various frequencies of 15 patients in whom accurate thresholds could be determined. This curve showed the plateau of hearing up to 1,000 cps, with the abrupt loss above this level. Only three cases heard above 2,000 cps, which could be a reflection of the degree of involvement of the dorsal and ventral cochlear nuclei. The author concludes that the degree to which the phylogenetically older low tone hearing pathway (ventral cochlear nucleus) is affected is directly related to the severity of the jaundice.

8950 INHERITABLE DISORDERS OF BILIRUBIN METABOLISM. (Eng.) Israel, J. B.; Arias, I. M (Albert Einstein Coll. Medicine, Bronx, NY). *Adv. Intern. Med.* 21:77-96; 1976.

8951 EFFECTS OF CARBOHYDRATE AND LIPID FEEDING ON THE PLASMA BILIRUBIN CONCENTRATION IN GILBERT'S SYNDROME [Abstract]. (Eng.) Gollan, J. L.; Bateman, E. C.; Billing, B. H. (Royal Free Hosp London, England). *Digestion* 12(4/6):256; 1975.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

8952 AFLATOXIN-POSSIBLE FACTOR OF LIVER DAMAGE IN CHILDREN. (Cze.) Dvorackova, I.; Brodsky, F.; Cerman, J. (Ustav patologicke anatomie, 500 36 Hradec Kralove, Czechoslovakia). *Cesk. Hyg.* 19(4):211-216; 1974.

Seven cases of fatal illness in children aged 3 days to 22 months were observed. In two cases, the illness had a clinical picture of an acute encephalitic syndrome, and in four cases, the course of the disease was prolonged, but the clinical symptoms were similar. The main morphological finding was brain edema and steatosis. In prolonged cases, the liver showed, together with steatosis, chronic changes (periportal and perilobular fibrosis and in one case, cirrhosis). Bacteriological and virological examinations were negative. A substance whose qualities corresponded to those of aflatoxin B_1 was chromatographically detected in the livers of the dead children. Only one similar report has been published. Very little is known about the effects of aflatoxin on humans, and published data concern cases observed in the tropics. Our observations indicate that even under temperate conditions, aflatoxin may be an etiological factor in some cases of liver damage, especially in children. It is not clear whether the intoxication occurs pre- or postnatally. The mother of two of the infants worked at a poultry selection center during both pregnancies and was probably in contact with alfatoxin-contaminated feeds. The toxin may have been transmitted to the children prenatally or in the mother's milk after birth. The proven occurrence o aflatoxin in the milk of cows given contaminated feed suggests the latter hypothesis, although in one of the cases, aflatoxin was present in the liver of a 3-day-old boy born prematurely.

8953 UNEXPLAINED JAUNDICE FOLLOWING NON-HALOTHANE ANAESTHESIA: A CASE REPORT. (Eng. Hart, S. M.; Fitzgerald, P. G. (St. Finbarr's Hosp. Douglas Rd., Cork, Ireland). *Br. J. Anaesth.* 47(12 1321-1326; 1975.

The case of a 62-yr-old man who developed unexplaine jaundice following the repeated administration of non-halothane anesthesia is presented. The patient had undergone amputation of the right leg for acute claudication 3 yr previously and presented with a gangrenous ulceration of the left hallux. He receiv atropine (0.5 mg, i.v.) and anesthesia (200 mg thiopentone followed by 75 mg suxamethonium chloride via endotracheal intubation) prior to an unsuccessful femoral angiogram. Anesthesia was maintained with nitrous oxide (8 l/min) and oxygen (4 l/min) delivered from a Boyle's apparatus fitted with a halothane vaporizer and a methoxyflurane vaporizer. A further 225 mg of suxamethonium chloride was given. The patient's fever persisted for 6 days, during

ich time he complained of nausea and upper abdomi-
l discomfort. Four days after his temperature
d returned to normal, a translumbar aortogram
sing sodium iothalamate) was carried out under
uroleptanalgesia with droperidol (7.5 mg) and
enoperidene (0.75 mg). After the procedure, the
tient again developed pyrexia; cephalothin, which
d been administered since the development of py-
xia after the first procedure, was continued. A
itti-Stokes amputation was performed for extensive
sease in the leg. For this operation, the patient
ceived atropine, thiopentone, suxamethonium chlo-
de, pancuronium nitrous oxide, and oxygen. Anes-
esia was supplemented with droperidol and fentanyl.
e neuromuscular block was antagonized by neostig-
ne preceded by atropine. The patient's tempera-
re increased, and he became jaundiced and confused
the 8th day after operation. Total bilirubin,
kaline phosphatase, SGOT, LDH, and SGPT levels
re all elevated. Hepatitis B antigen was not de-
cted. There was an increased γ-globulin fraction
the plasma proteins. The jaundice disappeared
adually over about 6 days, and pyrexia disappeared
a further 7 days; the liver function tests were
rmal 29 days after operation. Although halothane
s not administered in this patient, his symptoms
re similar to those in post-halothane jaundice.
e possible reasons for his jaundice include: leak-
e of halothane from the halothane vaporizer tubes,
e presence of sepsis, or the competition of methyl-
pa and the anesthetic drugs for the same micro-
mal enzymes involved in biotransformation.

54 LIVER INJURY CAUSED BY N-PROPYLAJMALINE BITARTRATE.

(Ger.) Henning, H.; Vogel,
-M.; Ihlenfeld, J.; Buchegger, K.; Luders, C. J.
linik Fohrenkamp BfA, 2410 Molln/Lauenburg,
stfach 13 80, W. Germany). *Z. Gastroenterol.* 13
):501-506; 1975.

o case reports of prajmaline management of toxic
allergic hepatitis are presented. A 47-yr-old
man under prajmaline treatment for arrhythmia
r 1 week presented with fever, icterus of skin
d conjunctiva, anorexia, and nausea. Diagnosis
s cholangitis with slight cholestasis and fatty
ver. Under suspicion of prajmaline-induced liver
mage, a challenge of 20 mg prajmaline was given
two successive days. A 3% eosinophilia and
nspicuous elevation of alkaline phosphatase, GLDH,
T, and GPT occurred within 24 hr. A 49-yr-old
man received prajmaline for management of extra-
stoles; GOT and GPT increases had not been in
idence after administration of other antiarrhyth-
c agents. Further tests with three doses of 20
prajmaline also showed biochemical profiles
pical of liver injury. Histology found edematous
rtal fields with fibrosis, lymphocytic infiltrates,
ominent eosinophilia, hypertrophy of intrahepatic
cts, and fatty vacuolization. Paraclinical
riables were normalized 15 days later, without
erapy. In a subsequent screening study, 4 of 27
tients on prajmaline also presented with elevated
rum enzymes. The medication history of patients
th suspected chronic active hepatitis should be
plored.

8955 LIVER DISEASE IN POLYVINYL CHLORIDE PRODUCTION WORKERS—CLINICAL AND LAPAROSCOPIC ASPECTS.

(Ger.) Marsteller, H. J.; Lelbach, W. K.; Muller, R.; Gedigk, P.; Lange, C. E. (Medizinische Universitatsklinik, D-5300 Bonn-Venusberg, W. Germany). *Leber Magen Darm* 5(5):196-202; 1975.

The clinical findings, laparoscopic data, and histology of liver damage in 44 employees of polyvinyl chloride manufacturing plants are discussed. The liver was palpable in 16 of 44, and there was a nodular or granulated liver surface in 25 of 44. Portal fibrosis was conspicuous in 25, most of it reticular, with septal invasion. Increased vascularization occurred in 20 workers; only 7 had frank portal hypertension. BSP retention was elevated in 34 (45-min mean of 10.5%), and 12 had a low-grade hyperbilirubinemia. SGOT increased transiently in 12 employees, SGPT in 13, and alkaline phosphatase in 8. Esophageal or fundic varices were found in 10 subjects. Thrombocytopenia, often with platelet dysfunction, was marked in 40 patients. Histologically, focal degeneration in hepatocytes, nuclear polymorphy or polyploidy, septal fibrosis, reticular collagenization, and sinusoidal cell proliferation were the predominant findings.

8956 MORPHOLOGICAL CHANGES OF THE LIVER AFTER CHRONIC VINYL CHLORIDE INTOXICATION.

(Ger.) Muller, R.; Bechtelsheimer, H.; Gedigk, P.; Marsteller, H. J.; Lelbach, W. K. (Pathologisches Institut der Universitat, D-5300 Bonn-Venusberg, W. Germany). *Leber Magen Darm* 5(5):204-208; 1975.

The liver biopsy results for 50 patients who had worked in polyvinyl chloride (PVC)-manufacturing plants are generalized. Necroses in cell assemblies were not found, but individual hepatocytes were hypertrophic and necrotic. About half the parenchymal cells showed some degree of fatty degeneration. The more recent the exposure, the more marked were the changes. Synchronous adaptation, chiefly milk-glass cytoplasm, was conspicuous. Hyperplasia also occurred, but it could not be related to exposure time; it was especially pronounced around the dilated sinusoids. There was either septal fibrosis of the portal fields or, more frequently, centrolobular collagenization of the sinusoid walls. The perisinusoidal collagen deposition did not resemble that of sclerosing hyaline necrosis or chronic hepatitis. The degree of fibrosis and collagenization varied directly with total exposure time. The most marked changes occurred in the sinusoidal cells. Nuclear modification was apparent in the larger lining cells after a 1-yr exposure. After 6-10 yr, there was chain proliferation of the lining cells, with increasing nuclear polymorphy. Hemangioendothelial sarcomas were found in 3 of 50 cases. The tumors extended along the sinusoids into the parenchyma, often polycentrically. There was a strong indication of transitional cell types between the atypical sinusoidal cells and tumor cells at the growing edges of the sarcoma. Individually, these cell alterations were nonspecific, but the combination might represent a specific VC syndrome.

8957 DOES SERUM HIGH-DENSITY LIPOPROTEIN (HDL) CONTENT CORRELATE WITH LIVER DAMAGE [Abstract]. (Eng.) von Lehmann, B.; Grajewski, O.; Oberdisse, E.; Arntz, H.-R. (Pharmakologisches Institut der Freien Universitat Berlin, Berlin, E. Germany). *Digestion* 12(4/6):324; 1975.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

8969 ETIOLOGICAL SPECTRUM OF POST-TRANSFUSION HEPATITIS. (Eng.) Knodell, R. G.; Conrad, M. E.; Dienstag, J. L.; Bell, C. J. (Div. Hematology/Oncology, Univ. Alabama, Birmingham, AL 35204). *Gastroenterology* 69(6):1278-1285; 1975.

Preoperative, acute, and convalescent sera were screened for evidence of hepatitis B and A virus, Epstein Barr virus (EBV), and cytomegalovirus (CMV exposure in 34 cardiac surgery patients developing post-transfusion hepatitis postoperatively and 20 randomly selected patients. Four hepatitis patien showed evidence of hepatitis B infection and three non-B hepatitis patients developed significant antibody titer rises to CMV. The blood transfusio requirement for these patients was significantly

ter than that required for either the remaining
titis patients or the nonhepatitis group
.001). No patient showed evidence of acute
titis A infection postoperatively in response
lood transfusions. EBV was not responsible for
cases of post-transfusion hepatitis. Laboratory
s defined a probable etiology in only 7 of 34
s and failed to implicate hepatitis A, EBV, or
in the majority of the non-B post-transfusion
titis cases. This suggests that identification
characterization of additional hepatitis-produc-
agents will be required to define further the
emiology of post-transfusion hepatitis and to
lop measures for its prevention.

CLINICAL, BIOCHEMICAL AND HISTOMORPHOLOGI-
CAL STATE OF THE LIVER IN 203 SUBJECTS CURED
CUTE VIRAL HEPATITIS. (Cro.) Kaljalovic, R.;
, M.; Bojanic, N.; Tasic, B. (Institut za Patolo-
i Sudsku Medicinu, Yugoslavia). *Zb. Vojnomed.*
33-37; 1974.

ical, biochemical, and histomorphological changes
he liver of patients cured of acute viral hepa-
is were studied; 203 men had suffered from acute
l hepatitis for 6 months to 15 yr prior to
study. A normal liver was found in 139 men
were examined histologically, even though some
physical changes (subicterus and enlarged liver
spleen), as well as changes in liver function
ts. Chronic persistent hepatitis was found
28 patients, and 2 men had chronic acute hepa-
is. Liver cirrhosis was found in 2 patients,
le 28 men had small residual histomorphological
nges of the liver. The changes were most often
the form of mild periportal liver infiltration.
re was no correlation between the clinical and
medical findings and histomorphological changes.

1 ACUTE AND CHRONIC HEPATITIS. (PART I).
(Ger.) Affolter, H.; Allemann, U.; Raber,
(Medizinische Abteilung, St.-Clara-Spital, 4058
l, Switzerland). *Praxis* 64(30):949-957; 1975.

current status of hepatitis B Australia antigen
sAg) and its role in acute viral hepatitis are
iewed. A group of 68 patients with acute viral
atitis (AVH) was 40% positive for HBsAg. In hepa-
is B serum, HBsAg is detectable 1-4 weeks before
clinical signs and remains 4-6 weeks after clini-
onset. The prodromal phase lasts 1-2 weeks before
onset of icterus and is characterized by nausea,
er, and arthralgia. The icteric phase begins
days after the first phase, and its clinical
ression results from direct hepatocyte insult.
nsaminase elevation begins 2 months after paren-
al and 3 months after oral infection; alkaline
sphatase is increased only in cholestatic involve-
t. Fulminating infection is indicated by sharp
irubin increases, sudden transaminase decreases,
a reduction in clotting factors II, V, and VII.
HBsAg remains elevated after AVH subsides in 3
ths, a transition to chronic hepatitis usually
urs. Antibiotics, vitamins, the flavonoid cya-
amol, and dietary intervention are without effect.
Corticosteriods should never be administered in uncomplicated disease, since they influence neither the degree of liver necrosis nor healing; they are associated with more complications and higher recurrence rates. The author recommends prednisolone (40-60 mg/day) only in refractory AVH. Mortality is about 1%. Of 52 of 68 patients followed, 5 developed chronic hepatitis, 2 developed active hepatitis, and 3 developed persistent chronic hepatitis. Prophylaxis with hyperimmune sera is recommended.

8972 ISOLATION AND CHARACTERIZATION OF HEPATITIS A VIRUS. (Eng.) Bradley, D. W.; Hollinger, F. B.; Hornbeck, C. L.; Maynard, J. E. (Phoenix Lab. Div., Public Health Service, Dept. Health, Education, Welfare, Phoenix, AZ). *Am. J. Clin. Pathol.* 65(5):876-889; 1976.

Current isolation techniques of hepatitis A virus (HAV) from human and chimpanzee stool, liver, and bile specimens, as well as comparative characterizations of HAV buoyant density properties of human and chimpanzee stool-derived particles are reviewed. Methods designed for the extraction and purification of HAV from large samples of stool and liver tissues are discussed in detail. Pooled stool suspended in water, veal infusion broth, and bovine serum albumin is stirred at 25 C, freeze-thawed four times, centrifuged once at 1,000 x *g*, centrifuged twice at 12,000 x *g*, and passed through a membrane filter of 0.45 μm pore size; the filtrate is concentrated sevenfold in an Amicon TCF-10 ultrafiltration system, dialyzed twice, and examined by immunoelectronmicroscopy. Immunoelectronmicroscopy of gradient fractions of HAV from human stool prepared on a five-step, discontinuous CsCl gradient revealed that the bulk of the HAV particles band in fractions with buoyant densities of 1.22-1.47; this suggests that the HAV particles belong to the enterovirus group. Passage and subpassage of human-derived stool suspension in chimpanzees markedly altered the apparent banding properties of the HAV particles on CsCl gradients. The finding of bimodal distributions of HAV particles in CsCl gradients for chimpanzee-derived samples may reflect the influence of the host's gut environment on the buoyant densities of the HAV particles. Immunoelectronmicroscopy and radioimmunoassay of bile collected both from the gallbladder and by T-tube cannulation of the common bile duct in chimpanzees revealed the presence of HAV. Two methods have been used for the extraction of HAV from infected chimpanzee liver tissue: high-speed homogenization of the tissue in a biocontained Omni-Mixer chamber, using phosphate-buffered saline of 1% in Triton X-100, followed by differential centrifugation of the homogenized material; and an aluminum oxide grinding procedure, also with 1% Triton X-100. A radioimmunoassay comparison of the two procedures revealed that the latter procedure yielded about five times more antigenic material than the former method. Purification of HAV from stool filtrates by polyethylene glycol precipitation and Sepharose 2B gel filtration yielded a significantly greater degree of purification than that obtainable by isopycnic banding of the preparation in CsCl. Sepharose gel filtration of liver extract did not result in extensive purification of HAV antigen activity, indicating that other techniques are needed to purify HAV from infected liver tissue.

8973 COAGULATION FACTORS IN THE DEVELOPMENT OF COMMON VIRUS HEPATITIS.

(Fre.) Thabaut, A.; Laverdant, Ch.; Durosoir, J.-L.; Voinesson, A.; Cristau, P.; Essioux, H.; Molinie, Cl.; Allard, P.; Roue, R. (Hopital d'Instruction des Armees Begin, F 94160 Saint-Mande, France). *Ann. Med. Interne (Paris)* 126(10):639-648; 1975.

A systematic study of coagulation variables in viral hepatitis patients is reported. The clinical sample included 104 subjects 18-25 yr of age. All had evolved toward normalization, 80 monophasically and 24 polyphasically (with rebound). Assay was also made of 100 healthy persons of equivalent age and 31 patients with alcoholic cirrhosis. Total plasma coagulability, as measured by cephalin-kaolin time, was maximal at the onset of hepatitis and persisted up to week 7, regressing only gradually thereafter. The prothrombin time was not significantly lower at the onset of the disease, and it returned to normal at the end of week 1. Factor VIII remained significantly elevated over control levels through week 2, reaching its maximum at the onset of hepatitis. Factor IX levels were insignificantly lower throughout. Thrombin time was higher in the hepatitis group up to week 5; its maximum was at the onset of disease. Fibrinogen levels were insignificantly lower among the cirrhotics and insignificantly higher in the hepatitis patients for 1 week, after which they declined to significantly lower levels by week 3. Factor XIII was the same in all subject groups. There was no evidence of arrested fibrinolysis in the hepatitis patients. Proactivator rates were reduced in the cirrhotics only at the onset of disease; they returned to normal in week 1. Plasminogen was also lower in the cirrhotics, but it was unaltered in the hepatitis patients. Antithrombin III was reduced among the cirrhotics and slightly elevated in the hepatitis group. There was no difference in any factor between the monophasic and polyphasic groups. Photometric assay showed a significant difference between the affected and healthy subjects in fibrin formation, suggesting defective polymerization of fibrin monomers.

8974 ROLE OF HBsAb IN DEVELOPMENT OF HEPATITIS.

(Eng.) Gomez de la Concha, E.; Hernandez-Guio, C.; Ortiz, F.; Hernando, L. (Fundacion Jimenez Diaz, Ave. Reyes, Catolicos 2, Madrid, 3, Spain). *Lancet* 2(7929):304-306; 1975.

To clarify the relation between the antibody to hepatitis B surface antigen (HBsAb) and the development of hepatitis in carriers of hepatitis B surface antigen (HBsAg), a sensitive passive hemagglutination assay was used to test for HBsAb. Sera of 45 healthy controls, 20 patients with acute type-B hepatitis, 32 household contacts of 14 HBsAg carriers, 31 hospital staff members working in high risk areas for acquiring HBsAg, 92 commercial blood donors whose sera were HBsAg-negative, 31 patients with chronic renal
failure, 66 patients with chronic hepatitis or l
cirrhosis, and 21 asymptomatic HBsAg carriers we
tested. HBsAb was found significantly less ofte
in the asymptomatic HBsAg carriers (24%) than in
HBsAg carriers with liver disease (60%, p<0.025)
Among the asymptomatic HBsAg carriers, all of th
five patients who had HBsAb had elevated SGOT va
ues, compared with only 6 of the 16 without anti
(p<0.01). Following an outbreak of type-B hepat
in 10 of a group of 41 patients and staff member
previously tested for HBsAb, it was found that h
titis had occurred in 7 of 18 patients who had n
had HBsAb and in only 3 of 23 patients who had p
existing antibody. This difference was even mor
significant when those individuals with antibody
titers of 1/27 or higher were compared with thos
whose titers were lower than 1/27. Of the 10 in
dividuals who developed hepatitis, only two beca
negative for HBsAg and had normal liver function
tests within 11 months after the appearance of s
toms. Among 20 patients with acute type B hepat
and no renal insufficiency or immunological dysf
tion, liver function tests returned to normal, a
HBsAg disappeared from the serum in all but one
tient within 11 weeks. These data suggest that
B hepatitis is endemic in the general population
Spain, and that immune response to HBsAg may be
essary for the prevention of the development of
liver damage in this disease. A good antibody r
sponse to HBsAg was found, however, in uremic pa
tients with hepatitis. It appears, therefore, t
immune mechanisms other than the humoral respons
may account for the pathogenesis of this disease

8975 IMMUNE REACTIONS TO HBsAg, HBcAg AND " ANTIGEN IN ACUTE VIRAL HEPATITIS AND I HBsAg CARRIERS WITH NORMAL AND PATHOLOGICAL LIVE

(Ger.) Meyer zum Buschenfelde, K. H.; Arnold,
Knolle, J.; Hess, G. (II. Med. Univ.-Klinik, La
beckstrasse, D-6500 Mainz, W. Germany). *Z. Gast
enterol.* 14(3):365-377; 1976.

Studies of the temporal relation between humoral
cellular immunity against hepatitis B (HB) antig
and the simultaneous behavior of HB surface anti
(HBsAg), HB core antigen (HBcAg), and e-antigen
serum or tissue were undertaken in patients with
viral hepatitis and in HBsAg carriers with and
liver disease. Clinical samples included 22 HBs
carriers with normal livers (group A), 13 patie
with acute viral hepatitis (group B), 6 patients
acute nonviral hepatitis (group C), and 12 HBsA
tive patients with chronic active hepatitis (gr
Only five patients in group A showed inhibition
stimulation in the presence of HBsAg; cell medi
immunity against human liver specific membrane
(HLMP) was present in two patients. Cell media
immunity against antinuclear, antimitochondrial
smooth muscle, and liver cell membrane antigen
antibodies did not occur. Antibodies to HBsAg
HBs) were not detected, but antibodies to HBcAg
HBc) were found in 10 of 10 and anti-e in 6 of
HBsAg, but not HBcAg, was demonstrated in hepat
cytoplasm in 16 cases. In group B, 12 cases sh
cell mediated immunity against HBsAg, although
HBsAg was radioimmunologically negative and no

ntibodies to the antigen 4-6 weeks after the
of disease. In 4-6 months, cell mediated
ity decreased and anti-HBsAg increased. A
ity of patients showed a constant immunity to
for several weeks of the disease. Anti-e and
igen were not found. In group C, antibodies to
and cell mediated immunity were absent. In
D, nine patients showed a cell mediated immunity
st HBsAg and HLMP for at least 18 months. HBcAg
nti-HBc were found in the nuclei of isolated
ocytes in all patients. The findings indicate
the immune reaction against virus, viral antigen,
irus-infected cell represents the pathogenetic
r of acute and chronic liver involvement, rather
hepatitis-B-virus itself.

A DOUBLE-BLIND TRIAL OF (+)-CYANIDANOL-3 IN VIRAL HEPATITIS. (Eng.) Berengo, A.;
ito, R. *In: New Trends in the Therapy of Liver*
ses. Proceedings of the International Symposium
Trends in the Therapy of Liver Diseases, Tir-
, *June 6-7, 1974.* Bertelli, A., ed. (New York:
ger): pp. 182-190; 1975.

le-blind trial of (+)-cyanidanol-3 for the
ent of viral hepatitis was performed with 117
ts, 56 of whom received 1.5 g/day of the drug,
of whom received a placebo for 40 days. No
icant differences were noted in either the dura-
f illness or convalescence between the two
. The drug caused a 15% more rapid decrease
al serum bilirubin in the treated patients.
nical, biochemical, or hematological side-
s were noted.

CHOLESTASIS DURING VIRUS HEPATITIS. (Fre.) Albot, G.; Toulet, J. (Centre de
enterologie de la Clinique Chirurgicale l'Hotel-
1, place du Parvis Notre-Dame, 75004 Paris,
). *Sem. Hop. Paris* 50(46):2853-2865; 1974.

rieties of cholestatic expression during viral
tis are reviewed. The initial cholestatiform
transient cholestatic episodes during the
al period and in persistent hepatitis, choles-
rm and cholestatic viral hepatitis, and the
viral and drug-induced etiology of cholestati-
epatitis are examined. Cholestatiform involve-
efers to cholestasis superposed on syndromes
enchymal or mesenchymal hepatitis and cytoly-
It occurs in the first few days of icterus and
etimes prolonged to the 9th or 10th day,
earing by the 12th. The short duration,
e of acute ductal change, early onset of
rative hepatocyte modification, and involve-
f the Golgi apparatus suggest abnormalities
atocyte transit and elimination of conjugated
in. The transient cholestatic episodes are
erized by piecemeal zones of hepatocyte
cation, small-ductule necroses, and low hepa-
glycogen. Special attention is given to the
f a cholestatic syndrome associated with
ymal and mesenchymal hepatitis and cytolysis
chlorpromazine management. A competitive phenomenon between chlorpromazine and viral infection is proposed, which would explain the icterus and the frequency of cholestatiform occurrences.

LIVER AND BILIARY TRACT

Chronic Hepatitis

8988 BIOCHEMICAL FEATURES OF ACUTE AND CHRONIC HEPATITIS. (Eng.) Skrede, S.; Blomhoff, J. P.; Gjone, E. (Inst. Clinical Biochemistry, Rikshospitalet, Oslo, Norway). *Ann. Clin. Res.* 8(3): 182-199; 1976.

The authors' experience with biochemical tests in acute and chronic hepatitis is reviewed, and the differential diagnosis of these diseases from other liver diseases is discussed. Serum alanine aminotransferase (ALAT) and aspartate dehydrogenase (ASAP) levels have been found to be increased in most patients with acute viral hepatitis, acute alcoholic hepatitis, active chronic hepatitis, chronic persistent hepatitis, and primary biliary cirrhosis. The ASAT/ALAT ratio was increased in 40% of patients with acute alcoholic hepatitis, 7% of patients with active chronic hepatitis, 6% of patients with primary biliary cirrhosis, 23% of patients with cryptogenic cirrhosis, and 59% of patients with alcoholic cirrhosis; this ratio was lowered in 32% of patients with acute viral hepatitis. The ornithine carbamyl transferase level (OCT) was raised in all patients with acute viral hepatitis, acute alcoholic hepatitis, chronic active hepatitis, chronic persistent hepatitis, and primary biliary cirrhosis. The transaminase levels were raised in all patients with acute alcoholic hepatitis, alcoholic cirrhosis, and alcoholic steatosis and in 93%, 96%, 70%, 95%, and 79% of patients with acute viral hepatitis, chronic active hepatitis, chronic persistent hepatitis, primary biliary cirrhosis, and cryptogenic cirrhosis, resp. Alkaline phosphatase was increased in 80%, 80%, 66%, 50%, 95%, 57%, 73%, and 28% of the patients with acute viral hepatitis, acute alcoholic hepatitis, chronic active hepatitis, chronic persistent hepatitis, primary biliary cirrhosis, cryptogenic cirrhosis, alcohol cirrhosis, and alcoholic steatosis, resp. In mos patients with acute or chronic hepatitis, the pre bumin and coagulation factor concentrations are l ered; the haptoglobin and complement C3 concentra tions are also frequently lowered. Increased tot cholesterol concentrations and free cholesterol, increased phospholipids and/or the presence of l protein X (LP-X) strongly suggest cholestasis, w as low total cholesterol concentrations, togethe with a relative increase of free cholesterol in plasma without the presence of LP-X, suggest par chymatous liver disease. An increase in immunog bulins belonging to a particular class is not di nostic of any particular liver disorder. Howeve the immunoglobulin G concentrations were often h in chronic active hepatitis. Smooth muscle anti bodies and antinuclear factors are most frequent elevated in chronic hepatitis. Quantitative tes of liver function, biochemical tests in the clas ation of liver disease, and test batteries in li diseases are discussed.

8989 RHEOLOGICAL INVESTIGATIONS IN CHRONIC ACTIVE HEPATITIS. (Ger.) Leonhardt, Bungert, H.-J. (Klinikum Steglitz, Freie Univers tat Berlin, D-1000 Berlin 45, Hindenburgdamm 30, W. Germany). *Z. Gastroenterol.* 13(6):588-593; 1

Plasma and whole blood viscosities in cases of a hepatitis (ACH) under corticoid management are c lated with laboratory data. The clinical sample cluded 12 type IIB and 5 type IIA patients witho

or therapy. Fluocortolone treatment (60 mg on day
40 mg on day 2, and 20 mg daily thereafter for 4
ks) was begun. The maintenance dose was 15-20
daily, depending on transaminase levels. Micro-
cosimetric and serum values were compared with
se in 20 normal patients without treatment. Pre-
atment plasma viscosity was significantly higher
the patient group, and correlated with immuno-
oulin G (IgG). The highest whole blood and
sma viscosity values and the most prominent
er dysfunction levels were almost exclusively
nd in type IIB disease (transaminase above 40 IU/
and hypergammaglobulinemia). After 4 weeks of
ocortolone, plasma viscosity was normal and the
m hepatic variables and whole blood viscosity
roved, with a significant correlation to dec-
ed IgG. Arterial ammonia occurred in only one
ent, and a positive normotest was found in two
ents. Hyperviscosity, which is attributed to
ated IgG, reduces the hepatic circulation and
equent oxygenation and leads to the typical
s of parenchymatous and stromal inflammation.

THE SERUM PROTEIN PROFILE IN CHRONIC HEPATITIS, CIRRHOSIS, AND LIVER CANCER. (Eng.)

matsu, S.; Kojima, J.; Okada, T. T.; Inai, S.;
ri, K. (Center for Adult Diseases Osaka, 3-
michi 1-Chome, Higashinari-ku, Osaka 537, Japan).
Hepatogastroenterol. 23(3):177-182; 1976.

larify the serum protein profile in liver dis-
s, the serum levels of immunoglobulin G (IgG),
IgM, transferrin, haptoglobin, α2-macroglobulin
, α1-antitrypsin (1AT), and α1-acid glycoprotein
) were determined by a single radial immunodif-
on method. One hundred and sixty healthy men, 38
ents with chronic active hepatitis, 30 patients
chronic inactive hepatitis, 30 patients with
ient cirrhosis, 40 patients with cirrhosis,
30 patients with primary liver cancer were tested.
ean levels of the three immunoglobulins and of
all liver diseases were significantly higher
those in the healthy subjects. The mean levels of
ere 1,347, 2,113, 1,652, 1,760, 2,116, and 1,888
in the healthy subjects, chronic active hepa-
, chronic inactive hepatitis, incipient cirrho-
cirrhosis, and primary liver cancer patients,
; the IgA levels were 244, 306, 298, 375, 428,
06 mg/dl, resp.; the IgM levels were 127, 204,
193, 212, and 230 mg/dl, resp.; and the 2M
s were 179, 325, 224, 335, 370, and 357 mg/dl,
Except in chronic active hepatitis, the mean
evels in the patients with liver disease were
significantly elevated in comparison with those
althy subjects. Haptoglobin levels in all but
hronic inactive hepatitis patients were signi-
tly lower than those in the healthy subjects;
evels were 148, 102, 102, 43, and 77 mg/dl in
ealthy subjects and the patients with chronic
e hepatitis, incipient cirrhosis, cirrhosis,
rimary liver cancer, resp. Transferrin levels
e patients with chronic active hepatitis and
ic inactive hepatitis (267 and 264 mg/dl, resp.)
significantly elevated in comparison with those
althy subjects (228 mg/dl) and the patients
other liver diseases. The mean lagp levels
significantly decreased in the patients with
chronic active hepatitis, incipient cirrhosis, and cirrhosis. The results suggest that increased transferrin levels may be used in distinguishing between chronic hepatitis and cirrhosis or primary liver cancer. It appears that as chronic hepatitis progresses toward liver cirrhosis, 1AT increases and haptoglobin decreases. The protein profile of liver cancer is a normal lagp level and an increased 1AT level. The α-globulin profile may be used for differential and prognostic diagnoses in liver diseases.

8991 INDICES OF CELLULAR IMMUNITY IN PATIENTS WITH CHRONIC ACTIVE HEPATITIS. (Rus.)

Severov, M. V.; Semendiaeva, M. E.; Traianova, T. G.; Mukhin, A. S. (I. M. Sechenov First Moscow Medical Inst., Moscow, USSR). *Sov. Med.* (5):107-112; 1975.

Sensitization to autologous and homologous liver tissue antigens and to hepatitis B antigen (HBAg)-containing serum was studied by the leukocyte migration inhibition (LMI) test in 17 patients with chronic persisting hepatitis, in 11 patients with secondary hepatopathies (unspecific ulcerative colitis, drug-induced diseases, functional hyperbilirubinemia, obstructive jaundice, opisthorchosis, and Hashimoto's disease), in 8 patients with alcoholic liver disease, and in 10 control subjects. The LMI test for homologous liver tissue was positive in 12 and negative in 5 patients with chronic persisting hepatitis; it was positive only in 3 of the 19 patients with secondary and alcoholic liver disease. Delayed type hypersensitivity to autologous liver tissue was observed in 4 of the 12 investigated patients with chronic persisting hepatitis. Significantly increased α-globulin and immunoglobulin A (IgA) levels were found in the 12 LMI-positive patients with chronic persisting hepatitis, while the α-globulin, IgA, IgM, and IgG levels were normal in the LMI-negative patients. Delayed type hypersensitivity to HBAg-containing serum was observed in 53.8% of the patients with chronic persisting hepatitis.

8992 HUMORAL AND CELL-BOUND IMMUNOLOGICAL REACTIONS IN CHRONIC HEPATITIS. (Ger.)

Maerker-Alzer, G.; Schumacher, K. (Medizinische Universitatsklinik, D-5000 Koln 41, Josef-Stelzmann-Strasse 9, W. Germany). *Leber Magen Darm* 5(4):132-139; 1975.

The correlation between immunologic criteria and differential diagnosis of chronic liver disease is explored. In highly active chronic hepatitis, the immunoglobulin G (IgG) level is high, IgA is moderate, and IgM is negligible. Nuclear antibodies are in 70-80% of all patients; mitochondrial antibodies are in <10%; smooth muscle antibodies are in 66%; vascular membrane antibodies are rare; and surface antigen is negative. In chronic hepatitis of low activity, IgG is moderate and IgA and IgM are negligible. Nuclear antibodies occur in <20% of the patients, mitochondrial antibodies in about 50%, smooth muscle antibodies in 30%, vascular membrane antibodies in 60%, and surface antigen is frequently positive. In primary biliary cirrhosis, IgG is moderately elevated, IgA is negative, and IgM is markedly elevated. Nuclear antibodies occur in 29% of the patients, mitochondrial antibodies in 92%, smooth muscle antibodies in 40%, vascular membrane antibodies in 0%, and surface antigen is negative. In alcoholic cirrhosis, IgG and IgA are extremely high, IgM is absent, nuclear antibodies are negligible, and mitochondrial, smooth muscle, and vascular membrane antibodies and surface antigen are negative. These patterns provide sufficient data to support a suspected disease, but they require histologic and other criteria to establish a diagnosis.

8993 INDICATIONS FOR AND RESULTS FROM IMMUNOSUPPRESSIVE THERAPY IN CHRONIC ACTIVE HEPATITIS IN CHILDREN. (Ger.) Baumann, W. (Universitats-Kinderklinik, D-6500 Mainz 1, Langenbeckstr. 1, W. Germany). *Monatschr. Kinderheild.* 123(8): 630-632; 1975.

Experiences with immunosuppressive management of pediatric chronic active hepatitis (ACH) were generalized. The clinical sample included 10 boys and 4 girls, 2.5-18 yr of age. All had elevated serum transaminase; 9 were Australia antigen-positive, 10 were positive to antinuclear factors, and 12 were positive to cell immune reactions. Pathological immunoglobulins were established in 11 children, and 9 were hypergammaglobulinemic. At biopsy, 9 children had prominent inflammation, and 10 were fibrotic. Initial therapy in seven patients included azathioprine (AZP, 2-3 mg/kg/day) and prednisone (PRN, 5-15 mg/day); serum was normalized in 3 months, the tissue in 1 yr. PRN was then interrupted, and AZP was reduced to 0.5-1.0 mg/kg/day; the patients have remained recurrence-free. Four children received PRN alone (2-3 mg/kg/day). Several recurrences were discovered, and exacerbation of the histology occurred in four, including development of progressive cirrhosis with portal hypertension in one case. In patients (adult or pediatric) with positive immunity and marked inflammatory signs, immunosuppressives are justified, particularly combined with glucocorticoids. Success is questionable in cases of incipient or progressive fibrosis. Australia antigen-positive ACH responds poorly to immunosuppressives, and rapid fibrosis is frequent.

8994 IMMUNOSUPPRESSANTS IN CHRONIC LIVER DISEASES (LITERATURE REVIEW AND NEW DATA). (Rus.) Podymova, S. D.; Nasonov, E. L. (I. M. Sechenov First Moscow Medical Inst., Moscow, USSR). *Ter. Arkh.* 48 (3):40-48; 1976.

Studies on the therapeutic effectiveness and side-effects of immunosuppressants in chronic liver diseases are reviewed, and new therapeutic data on the use of azathioprine in 11 patients with chronic cholangiolitic hepatitis and in 9 patients with chronic persisting hepatitis are presented. Initial signs of liver cirrhosis were observed in five patients with cholangiolitic hepatitis. The azathioprine doses ranged from 25 to 150 mg/day, being 50-100 mg/day in most cases, and were combined with 5-15 mg of prednisolone. The duration of the therapy was up to 1 yr in 11 cases and up to 2 yr in 9. The azathioprine therapy had a favorable clinical effect (alleviation of pruritus) in seven patients with cholangiolitic hepatitis; it was ineffective in three, and the effect was doubtful in one. The all viation of pruritus appeared usually 7-14 days afte the initiation of therapy. Favorable clinical chan were observed in all patients with chronic persisti hepatitis. The azathioprine therapy caused a signi icant reduction of the transaminase and alkaline phosphatase activities and of the immunoglobulin M (IgM) and IgG levels. The phytohemagglutinin test revealed an increased lymphocyte blast transformation index in all cases. The duration of the remission was up to 8 months in 2 cases, up to 6 months in 1 case, up to 4 months in 11 cases, and up to 2 months in 3 cases. Azathioprine showed no marke advantage over prednisolone in terms of prognosis. The negative effect observed in three cases was du to the hepatotoxicity of the preparation, which manifested itself in jaundice, an increased biliru level, and increased transaminase activity. Thrombocytopenia was observed in 10 cases, and fever wa seen in 1. The findings indicate the therapeutic value of azathioprine, preferably combined with pr nisolone, in the treatment of chronic liver diseas involving pronounced immune disorders.

8995 OXYPROLINE EXCRETION IN CHILDREN WITH CHRONIC DISEASES OF THE LIVER. (Rus.) Zhivitsa, L. V.; Safonova, E. S. (Central Inst. Po graduate Medical Studies, USSR). *Vopr. Khr. Mater Det.* 21(5):64-67; 1976.

Oxyprolinuria was studied in 14 children with chro persisting hepatitis, in 8 children each with chro aggressive hepatitis and liver cirrhosis, and in 1 children with extrahepatic form of portal hypertension and secondary liver fibrosis. The patients were aged 3-15 yr. The length of the disease rang from 6 months to 10 yr. Marked correlation was established between the severity and activity of the hepatopathy and the oxyprolinuria. The oxyprolinuria was significantly and considerably increas during the exacerbation of hepatitis and cirrhosis and was reduced to slightly below normal levels du remission. The oxyprolinuria was slightly below normal in secondary liver fibrosis. The oxyprolin test proved to be more reliable than the thymol test or proteinograms in the determination of the status of the connective tissue in chronic persist and aggressive hepatitis and in liver cirrhosis.

8996 CHRONIC ACTIVE HEPATITIS AND OXYPHENISATIN. (Fre.) Berthelot, P.; Dhumeaux, Metreau, J.-M. (Unite INSERM U-99, Hopital Henri-Mondor, F 94010 Creteil, France). *Arch. Fr. Mal. App. Dig.* 64(8):711; 1975.

The case history of a 69-yr-old woman with oxyphe sitin (OX)-induced liver injury is presented. Icterus of 6 weeks duration, marked hepatomegaly, no splenomegaly, and no sign of hepatic insuffici cy were noted. For 15 yr the patient took the equ alent of 20-30 mg OX for chronic constipation. T following paraclinical data were established: bi rubin, 90 mg/l; SGPT, 380 IU; alkaline phosphatas

3 IU; and γ-globulin 33 g/1. Hepatitis B surface
ntigen was negative. Laparoscopy revealed a nodu-
ar liver, biopsy, significant portal sclerosis and
lffuse lymphoplasmocytic infiltration. Although
X use was interrupted, the patient died 2 months
ater of gastrointestinal hemorrhage. The diagnosis
as chronic active hepatitis.

)97 DIFFUSE RETROPERITONEAL FIBROSIS, CHRONIC
HEPATITIS, AUSTRALIA ANTIGEN: POSSIBLE
LE OF THE ANTIGEN IN THE INDUCTION OF FIBROSIS.
re.) Thomas, M.; Boccon-Gibod, L.; Pradalier, A.
ervice d'Endocrinologie-Nutrition, Hopital Saint-
toine, 184, rue du Fg St-Antoine, 75012 Paris,
ance). *Med. Chir. Dig.* 5(2):79-82; 1976.

e role of Australia surface antigen (HBsAg) in
patitis fibrogenesis is examined in a woman present-
g with a history of weight loss, asthenia, arthral-
a, and right lumbar pain. Initially, the SGPT was
0 Frankel units (FU), with subsequent febrility
d transient icterus; it rose to 3,200 FU before
uctuating. The patient was positive for HBsAg
/70). There was leukocytosis, but the liver was
t palpable. Bilateral ureteral stenoses were
tected. The stenoses and lumbar pain receded under
mg prednisolone, and the SGPT and alkaline phos-
atase levels returned to normal. The HBsAg persist-
, with slight hepatocyte insult and minimal infilt-
tion. Maintenance on 30 mg prednisolone normal-
ed all paraclinical variables, but HBsAg remained
sitive (1/16) and the hepatitis persisted. Reduc-
on of prednisolone to 10 or 15 mg resulted in SGPT
evations; HBsAg was positive (1/4). Six months
er, HBsAg increased to 1/128 and the liver showed
onic persistent hepatitis; all other variables
e stable. It is suggested that corticotherapy
presses host-antigen immune complex formation,
owing persistence of the virus and its hepatic
ects.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

3 HEPATOCELLULAR HYALIN AND ITS CLINICAL SIG-
NIFICANCE. (Rus.) Mansurov, K. K. (Tad-
k Inst. Gastroenterology, Dushanbe, USSR). *Ter.*
h. 48(3):48-56; 1976.

er biopsy was performed on 168 alcoholic patients.
24 patients with steatonecrosis, 4 showed Mallory
ies, and 3 of these showed necrotic changes and cellular infiltration. Eleven patients without Mallory bodies demonstrated only a slight degree of necrosis and infiltration. Chronic hepatitis was diagnosed in 35 patients. Clinical manifestations were more severe in the patients with Mallory bodies: 10 of 13 patients with Mallory bodies had jaundice, as opposed to 5 of 22 patients without them. Necrosis of the liver was observed in all patients with

LIBRARY U. OF I.

Mallory bodies and in only 10 patients without them. Of 107 patients with alcoholic cirrhosis, 70 had Mallory bodies. Jaundice, ascites, and fever were more frequent among the patients with alcoholic hyaline. This study supports the view that alcoholic hyaline is a frequent, but not specific, component of the parenchymal injury of the liver. Its presence may indicate the imminence of severe hepatic disease.

9004 RENAL TUBULAR ACIDOSIS AND ALCOHOLIC LIVER DISEASE. (Fre.) Vesin, P.; Gouerou, J.; Dervichian, M.; Agar, D.; Azogui, M.; Cattan, D. (Faculte de Medecine de Creteil, Service de Medicine et Hepato-Gastro-Enterologie, Nouvel Hopital, F94190 Villeneuve-Saint-Georges, Creteil, France). *Arch. Fr. Mal. Appar. Dig.* 65(3):209-214; 1976.

The relation of complete tubular acidosis to alcoholic liver disease was explored in two patients. A 40-yr-old chronic alcoholic presented with hypokalemia, natremia, chloremia, and hepatomegaly. The amino aciduria, phosphaturia, and glycosuria results were normal. The ammonemia level was normal; urea protein was 70 g/l. Both β- and γ-globulins were elevated. A 45-yr-old chronic alcoholic with a history of disorientation and motor dysfunction presented with hepatomegaly, hypokalemia, creatinemia, a total protein of 70 g/l, and only slightly elevated γ-globulin. The kalemia, chloremia, blood urea, creatinemia, and natremia were exacerbated by 140 mEq of K ion. Liver biopsy found a massive steatosis and annular cirrhogenic sclerosis. The amino aciduria, phosphaturia, and glycosuria were normal. Neither patient showed evidence of autoimmune disease. It is inferred that the two patients could not secrete H ions from the distal tubules.

9005 MACROCYTOSIS IN CHRONIC ALCOHOLIC HEPATITIS. (Fre.) Buffet, C.; Chaput, J.-C.; Albuisson, F.; Subtil, E.; Etienne, J.-P. (Service d'Hepatologie et de Gastroenterologie, Hopital Antoine-Beclere, F 92140 Clamart, France). *Arch. Fr. Mal. App. Dig.* 64(4):309-315; 1975.

The frequency of macrocytosis in acirrhotic chronic alcoholic hepatitis (ACAH) was compared in various patient groups relative to mean corpuscular volume (MCV). The samples included 55 patients with ACAH (group 1), 10 chronic alcoholics with histologically normal livers (group 2), 13 acute alcoholics without hepatomegaly (group 3), 23 patients with nonalcoholic chronic hepatitis (group 4), and 50 alcoholic cirrhotics (group 5). The MCV of 45 of 55 group 1 patients was elevated to 103.8 μm^3 (99-117) 48 hr after hospitalization. The transaminases were also raised in 48 of 55. BSP was normal in 18 of 43, reduced in 9 of 43, and pathologically lower (0.043-0.092) in the remaining 16. Histology showed some degree of steatosis in all cases and fibrosis in 34 55 patients. There was no correlation between transaminase elevation, BSP depression, or steatosis and MCV. The MCV of group 4 was normal in 21 of 23 and significantly lower ($p<0.001$) at 93.4 μm^3 than group 1. An increased MCV can be found in chronic alcoholics with histologically normal livers. Group 3 showed no MCV elevation. In group 5, 44 of 50 had a increased MCV (105.8 μm^3). During hospitalization, the macrocytosis in 24 group 1 patients with an MCV greater than 100 μm^3 decreased within 15 days if the patient became abstinent. MCV is concluded to be a suitable index for chronic alcohol screening.

LIVER AND BILIARY TRACT

Cirrhosis

9010 A RATIONAL APPROACH TO THE TREATMENT OF ASCITES. (Eng.) Arroyo, V.; Rodes, J. (Hospital Clinico y Provincial, Univ. Barcelona, Barcelona, Spain). *Postgrad. Med. J.* 51(598):558-562; 1975.

Information concerning the treatment of ascites is reviewed, with particular emphasis on a study in which 55 cirrhotic patients were classified according to their ability to excrete sodium and free water. The glomerular filtration rate (GFR), rena

sma flow (RPF), free water clearance (after an
. water load of 20 ml/body weight), plasma sodium
centration, and urinary sodium concentration were
ermined after 7 days of bed rest and low salt in-
e. Twenty-one patients were losing ascites after
7-day period; these patients had a high mean
nary sodium concentration (82.3 mEq/1) and were
sidered "salt tolerant." The other 34 patients
e considered salt intolerant and had a signifi-
tly lower urinary sodium concentration (7.7
/1). The criteria of classification with regard
renal capacity to excrete free water were ob-
ned after plotting free water clearance against
sma sodium concentration. When free water clear-
was less than 1 ml/min, overhydration and hy-
tremia usually occurred; patients with free
r clearance greater than 1 ml/min were, there-
, considered water tolerant, and those with
water clearance lower than 1 ml/min were con-
red water intolerant. On the basis of these
eria, there were three groups of patients:
p 1, 21 patients who were water and salt toler-
group 2, 17 patients who were water tolerant,
salt intolerant; and group 3, 17 patients who
water and salt intolerant. Groups 1 and 2 had
tively good renal function. There were no sig-
cant differences between these two groups in
and mean RPF (686 ml/min for group 1 and 552 ml/
for group 2). Group 3 had a significantly lower
and RPF (363 ml/min, $p<0.001$). Group 1 patients
ascites on bed rest and low salt intake alone,
this process was accelerated by the administra-
of distal diuretics. All patients were dis-
ged without ascites. Group 2 patients needed
etics because of the low urinary sodium concen-
ion, but all but one showed a positive response
istal diuretics. Four patients died, and this
ality was significantly higher than in group 1
.05). In group 3, only 5 of 15 treated patients
onded to treatment, and the remaining patients
. An additional patient among the 17 survived;
mortality was significantly higher than in
2 ($p<0.05$).

COMPARISON OF THE INDICES OF THE BROMSUL-
PHALEIN TEST, THE SERUM CHOLINESTERASE
HE GALACTOSE TEST BY HEPATIC CIRRHOSIS. (Eng.)
ev, M. (I. P. Pavlov Higher Medical Inst.,
iv, Bulgaria). *Folia Med.* 16(3):151-156; 1976.

iagnostic values of the BSP test, serum cholin-
ase activity (SCE), and the galactose test (GT)
atients suffering hepatic cirrhosis were com-
. The BST and SCE were assessed simultaneously
patients, the BST and GT were assessed in 100
nts, and the GT and SCE were assessed in 57
nts. There was a slight, inversely proportional
lation between BST and SCE, and the changes of
indices were markedly parallel. BST was posi-
in 94% of the cases and SCE was positive in 85%.
arallelism between the values of BST and SCE
ore marked in the patients with ascites and
marked in those without ascites. The GT was
ive in 42%, mildly positive in 19%, and nega-
in 39%. These data and the 94% positive BST
t show that the excretory function of the liver
is more impaired than the carbohydrate function. Therefore, the diagnostic value of the BST is superior to the GT. The diagnostic value of SCE (82%) was also much better than that of the GT (59%). It is concluded that in hepatic cirrhosis the excretory function of the liver is the most affected, followed by the enzyme-synthesizing function and then the carbohydrate function. Thus, the BST test is the most useful, followed by lowered serum cholinesterase activity and the GT, in the diagnosis of hepatic cirrhosis.

9012 SOME COMMENTS ON THE ACTUAL ASPECT OF "PRIMARY BILIARY CIRRHOSIS." (Fre.)
Sotgiu, G. (Istituto di Clinica Medica Generale e Terapia Medica dell'Universita di Bologna, Bologna, Italy). *Ann. Gastroenterol. Hepatol.* 11(3):169-195; 1975.

The current status of primary biliary cirrhosis is reviewed. The nosology, histology, immunology, etiology, clinical picture, differential diagnosis, physiopathology, and therapy are examined, and the relation of destructive nonsuppurative chronic cholangitis, active chronic hepatitis, and intrahepatic cholestasis to primary cirrhosis is explored. The orientation is relatively novel. A distinction is made in cirrhotic pathology between obstructive involvement of the canaliculi and ductules by solid luminal material and destructive involvement of the larger ductules and ducts by the disappearance or obliteration of littoral elements. Destruction is generally distal to obstruction and is a result of cholestasis. Abnormal bile acids are interpreted as both the cause and effect of cholestasis, leading to biliary stasis, stromal inflammation, fibrosis, and cirrhosis. The primary condition is construed as an idiopathic biochemical lesion probably based on a congenital enzymatic defect that develops into an icteric cholestasis, in contrast to extrahepatic cholestasis, which is icteric throughout its course. The disease could be sex-linked, since a female predominance has been reported. For several reasons, among which is the similarity of biliary cirrhosis with collagen disease, a primary genetic immunological defect is considered probable.

9013 THE "UREA INDEX" AS A MARKER OF PORTAL FLOW DIRECTION IN CIRRHOSIS OF THE LIVER.
(Eng.) Hazenberg, H. J. A.; Gips, C. H. (Interne Afdeling, St. Jozefziekenhuis, Deventer 6600, Netherlands). *Acta Hepatogastroenterol. (Stuttg.)* 23(2):93-100; 1976.

The hepatic venous/arterial ratios were studied in 50 controls and 52 patients with cirrhosis to define the optimal interval for determining the ratio of hepatic venous increment/arterial urea increment and to compare the results with other parameters in cirrhosis. Arterial and hepatic venous blood samples were drawn at intervals up to 120 min following p.o. loading with 20 g of urea. The increment of the hepatic venous urea from time zero, divided by the increment of the arterial urea was calculated for all intervals. The 0-15 min ratio was defined as the urea index. Urea indices were lower in patients with cirrhosis ($p<0.001$); the median ratio of the controls was 1.8, compared with 1.45 for the cirrhosis patients. Unlike abnormal ammonia tests found in the whole range of urea indices, normal ammonia tests were found in patients with normal indices only ($p<0.01$), and inices below 1.25 invarably were associated with an abnormal ammonia test ($p<0.001$). An urea index of 1.2 or less was correlated with a hepatic sinusoidal pressure (HSP) value of 8 mm Hg or more (sign test, $p<0.01$). The inverse was not found. In patients with an index of 1.2 or less, ascites was more often present ($p=0.03$) than in patients with a higher index. Ascites was correlated with an HSP of 8 mm Hg or more ($p<0.01$). It is concluded that a normal HSP combined with a low urea index may indicate a diversion of the portal blood flow due to extrahepatic causes.

9014 ISOTOPIC DYNAMIC STUDY OF FIBRINOGEN METABOLISM IN LIVER CIRRHOSIS. (Fre.)

Delmont, J.; Bisset, J.; Rampal, P.; Camous, J.-P.; Faure, X. (Centre d'hepato-gastro-enterologie, 4, avenue Reine Victoria, 06100 Nice, France). *Nouv. Presse Med.* 5(25):1567-1569; 1976.

Fibrinogen metabolism was studied in cirrhotic patients. The subjects included 57 patients with varying degrees of hepatic insufficiency and 25 controls without liver or blood dyscrasias. The fibrinogen was labeled with ^{125}I, and the test was followed for 3-8 days. The biological period was lower in 49% of the cirrhotic group compared with 8% of the controls ($p<0.0001$). The plasma pool was also lower in 54% of the cirrhotic group compared with 8% of the controls. Four homogeneous populations emerge if the biological period is plotted against the plasma pool and the control and cirrhotic groups are combined. In group 1, consisting of 22 of 25 controls and 13 cirrhotics, the biological period and plasma pool were normal. In group 2, 13 cirrhotics and 1 control, the period was diminished and the pool was normal. In group 3, 16 cirrhotics and 1 control, the pool was reduced and the period was normal. In group 4, 15 cirrhotics and 1 control, both the period and the pool were diminished. In nine patients, including three from group 2 and six from group 4, heparin significantly raised the labeled fibrinogen period from 0.4 to 1.1 days, or from 15% to 48% of initial values ($p<0.01$). Neither the plasma pool nor the percent of plasma pool catabolized was significantly changed. This procedure provides an index of therapeutic effectiveness in managing consumption coagulopathies in cirrhosis.

9015 GASTRIC ACID SECRETION AND BASAL GASTRINEMIA IN CIRRHOSIS. (Fre.)

Bekhti, A.; Brassinne, A. (Rue Jean d'Outremeuse 79, B-4000 Liege, Belgium). *Rev. Fr. Gastroenterol.* (120):29-38; 1976.

Stimulated and basal gastric acid secretion and fasting gastrinemia were assayed in 21 patients with liver cirrhosis. Basal secretion was higher than normal (6 mEq/hr) in only three patients. One was a 69-yr-old alcoholic with a recent history of cirrhosis plus ascites and duodenitis; he had a basal secretion of 6.55 mEq/hr. The second was a 36-yr-old man with hepatitis, icterus, ascites, duodenal ulcer, and a secretion of 8.21 mEq/hr. The third patient was a 64-yr-old man with hepatitis, recent cirrhosis, normal gastric radiology, and a secretion of 11.43 mEq/hr. After pentagastrin stimulation, 4 of 17 patients showed either reduced secretion or none; after histamine stimulation, 1 of 4 patients showed reduced secretion. Three patients registered increases after pentagastrin. Fasting gastrinemia was within the normal range (39 pg/ml) for all patients. There was no correlation between variations in basal or stimulated acid secretion and gastrinemia or between these variables and the age or state of the cirrhosis. In one case of decompensated cirrhosis, pentagastrin stimulation increased acid secretion from 7.9 to 16.88 mEq after 1 yr.

9016 POTASSIUM METABOLISM AND DIURETICS ADMINISTRATION IN LIVER CIRRHOSIS. (Eng.)

Vesin, P. (31 rue de Moscou, 75008 Paris, France). *Postgrad. Med. J.* 51(598):545-548; 1975.

Changes in potassium metabolism in patients with cirrhosis, and the use of diuretics in the treatment of these patients, are reviewed. In the initial state of cirrhosis, salt and water retention are mild and transient, overt edema and ascites are absent, urinary output of K (Ku) and serum K (Ks) levels are normal, and a significant reduction of exchangeable potassium (Ke) has been noted in only a few cases. Stage 2 of cirrhosis is characterize by a marked salt and water retention, ascites, and edema (mainly the result of aldosterone hypersecretion). Ks is either normal or at the lower limit of normality; the Ku can be slightly increased or decreased or normal. In the third stage of cirrhosis, Ks sharply increases (sometimes reaching values above 5.5-6 mEq/l), Ku falls to figures sometimes below 20 mEq/24 hr, and Ke is markedly decreased, entailing a poor prognosis. Urinary K loss, which results indirectly from aldosterone hypersecretion, does not appear to be a major factor in the severe Ke reduction. A major hazard of diuretic therapy of cirrhotics, hypokalemia-induced portacaval encephalopathy, has been elimin ated by the discovery of K-sparing diuretics (spir nolactone, triamterene, and amiloride). The use of glucorticoids (especially prednisone) as diuretics also does not lead to hyperkalemia. The effects of the K-sparing diuretics on K metabolism are limited. They may moderately enhance Ku; following cessation of therapy, a rebound in Ku may b noted; and Ke may continue to decrease during thei administration, indicating an aggravation of the underlying disease. In addition, the K-sparing diuretics do not suppress the inability of the cel to retain or bind K. A rise in Ks and/or Ke durin amiloride administration does not prevent the ele vation of plasma renin activity, usually induced b volume and/or Na depletion.

LIBRARY U. OF I. [illegible]

7 CYTIDINE-5'-MONOPHOSPHATE-N-ACETYLNEURAMINIC
ACID. ASIALOGLYCOPROTEIN SIALIC ACID TRANS-
ASE ACTIVITY IN LIVER AND SERUM OF PATIENTS WITH
ENILE HEPATIC CIRRHOSIS AND α-1-ANTITRYPSIN DEFI-
NCY. (Eng.) Kuhlenschmidt, M. S.; Peters, S. P.;
kard, O. D.; Glew, R. H.; Sharp, H. (Dept. Bio-
mistry, Univ. Pittsburgh Sch. Medicine, Pitts-
gh, PA 15261). *Biochim. Biophys. Acta* 429(2):
-373; 1976.

um sialyltransferase (ST) activity was measured
the serum of six patients (aged 8-13 yr) with
-antitrypsin deficiency and hepatic cirrhosis.
six patients exhibited significantly decreased
um ST activity; it was only 50% that of healthy
iatric controls and 30% that of pediatric patients
n liver disease unrelated to α-1-antitrypsin
iciency. Family members who were homozygous for
-antitrypsin deficiency, but without hepatic
rhosis, did not show serum ST deficiency, and
ther did patients with various other liver dis-
es. Assays performed on a liver homogenate from
atient with α-1-antitrypsin deficiency and hepatic
rhosis did not show a deficiency in liver ST
ivity. A comparative kinetic analysis of serum
liver ST activity in normal and afflicted indi-
uals did not detect differences in substrate af-
ities that would explain a decrease in functional
capacity in individuals with α-1-antitrypsin
iciency and hepatic cirrhosis. This decrease in
um ST activity may result from extensive liver
age involving hepatic accumulation of α-1-anti-
psin.

3 OPERATIONS STIMULATING THE REGENERATION OF
LIVER IN CIRRHOSIS. (Rus.) Nartsissov,
7. (Kalinin Medical Inst., Kalinin, USSR). *Klin.*
. (2):30-33; 1976.

erience with hepatectomy to stimulate the regenera-
n of the liver in cirrhosis is presented on the
is of surgery on 34 patients. Laennec's cirrhosis
diagnosed in 27 patients, postnecrotic cirrhosis
3, and mixed cirrhosis in 4. Nine patients were
a compensated state at surgery; 25 were subcom-
sated, of which 12 were close to being decompen-
ed. The resection of segments II and III of the
lobe was anatomically most convenient, and was
formed in 30 cases. The weight of the resected
er tissue ranged from 28 to 550 g, depending on
size of the liver. Omentohepatopexy was performed
tionally in 24 cases for hemostasis and to improve
hepatic perfusion. Omentohepatodiaphragmopexy
performed in eight cases, and hypersplenism
essitated ligation of the splenic artery in five
es. Splenectomy was performed in six cases.
tes in the anamnesis necessitated Kalb's opera-
n in 13 cases. The severe postoperative complica-
ns included seepage of ascitic liquid from the
nd, oliguria, meteorism, pneumonia, acute hepato-
l failure, blood clotting disorders, and bleeding
n esophageal and gastric veins. The postoperative
ality was 13 of 34 cases; it was due to fibrino-
c hemorrhage in 5 cases, to acute hepatorenal
ure in 4, to bleeding from varicose veins of the
hagus and stomach in 2, to purulent pleuritis with subsequent acute hepatic failure in 1, and to peritonitis in another. Eight patients are in good condition, and another five are in satisfactory condition 0.5-6.5 yr after surgery. During this period, two patients died of acute hepatorenal failure, and one each of esophageal bleeding, peritonitis, pneumonia, and liver cancer. Reduction of the cirrhotic changes was observed at autopsy or surgery in four patients 2-3.5 yr after hepatectomy. The findings indicate that hepatectomy is indicated for compensated and subcompensated cirrhosis without varicose veins in the esophagus and stomach and esophageal and gastric hemorrhages in the anamnesis.

9019 CIRRHOTIC TRANSFORMATION OF BESNIER-BOECK-SCHAUMANN SYNDROME: ANATOMO-CLINICAL STUDY. (Fre.) Chomette, G.; Sarrazin, A.; Sors, Ch.; Emerit, J.; Auriol, M. (Service d'Anatomie pathologique, CHU Pitie-Salpetriere, 47, boulevard de l'Hopital, F 75634 Paris Cedex, France). *Ann. Med. Interne (Paris)* 127(2):101-107; 1976.

The development of cirrhosis in a patient with Boeck's sarcoid is reported. A 69-yr-old woman with an unexceptional medical history was hospitalized for recurrent bronchopathies. She was hepatomegalic, and her sedimentation rate was elevated. Bronchoscopy and laparoscopy showed identical punctiform granulations without cirrhotic nodules on the bronchial mucosa and liver surface, resp. The diagnosis was sarcoidosis. Subsequent biopsy confirmed the development of a granulomatous sarcoid with incipient cirrhosis. There was hypergammaglobulinemia and an abnormal flocculation test. Liver function was normal 1 yr later, except for elevation of BSP and alkaline phosphatase levels. The hepatomegaly was unchanged the following year, and signs of incipient portal hypertension, positive thymol, and BSP appeared. Persistent hepatomegaly, without splenomegaly or ascites, was found 1.5 yr later. The patient was anorectic and in a diminished state. A sudden hematemesis was followed by melena. Fibroscopy found ruptured esophageal varices; hemorrhaging continued despite transfusions. An onset of icterus was followed by death in hepatic coma under hypoalbuminemia and elevated alkaline phosphatase levels (50 Bodansky units). Autopsy found multiple sarcoidosis (lung, spleen, liver, kidney, colon, nodes, pericardium, ovaries, marrow, and pancreas and the pituitary, thyroid, and salivary glands). Hepatic nodules, some florid and some sclerotic, were scattered irregularly through the parenchyma. Many hepatocytes were lysed and cholestatic. There was massive periportal sclerosis with parenchymal diffusion and no evidence of regeneration. Sarcoid granulations were also found on the colonic mucosa.

9020 HEMODYNAMIC ELUCIDATION OF PORTAL HYPERTENSION. (Ger.) Paumgartner, G. (Institut fur Klinische Pharmakologie, Universitat Bern, CH-3010 Bern, Murtenstrasse 35, Switzerland). *Z. Gastroenterol.* 13(Suppl.):113-119; 1975.

A review of the most important methods currently in clinical use for preoperative hemodynamic clarification of patients with liver cirrhosis is presented, with emphasis on their diagnostic and therapeutic roles. Hepatic vein catheterization is the pressure measurement of least risk; it contributes to establishing a diagnosis of portal hypertension. Advantages and disadvantages of various methods, including clearance and dye-dilution, for liver perfusion measurement are discussed. The dye extraction method, based on Fick's law, is the current procedure of choice. The diagnostic value of perfusion in cirrhosis is relatively small, due to the extraordinarily wide distribution of individual values; it is not a determiner of patients for portacaval shunt operations. The author prefers gauging arterial vascularization by angiographic reading of the hepatic artery diameter and the extent of collateral circulation.

9021 ERRORS IN SURGERY FOR PORTAL HYPERTENSION. (Rus.) Samofalov, V. P. (Volgograd Medical Inst., Volgograd, USSR). *Khirurgiia (Mosk.)* (4): 103-108; 1976.

Diagnostic and surgical errors in 230 patients with portal hypertension were analyzed. Acute cholecystitis (five cases), appendicitis (three cases), peritonitis (two cases), acute pancreatitis (two cases), renal colic (two cases), and paranephritis and intestinal obstruction (one case each) were erroneously diagnosed as liver cirrhosis. Hemorrhage due to portal hypertension was sometimes erroneously attributed to peptic ulcer, leukemia, hemophilia, gastric and hepatic tumors, chemical burn, and Werlhof's disease. Indication of surgery was established on the basis of erroneous diagnosis of hydatid disease of the liver and spleen in six cases and of acute abdomen in two. The surgical experience indicates that splenectomy is not indicated at the dystrophic stage of portal cirrhosis and in the absence of hypersplenism. Omentohepatopexy or omenorenopexy is insufficient in cases of emergency splenectomy. To prevent postoperative hemorrhage from dilated esophageal veins, the esophageal veins should be excluded from the portal vein system by the modified version of Tanner's operation. Splenorenal anastomosis is recommended for dilated esophageal veins with hemorrhage, but even this anastomosis may not prevent hemorrhage in exacerbated cirrhosis.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

9047 ANATOMIC VARIATION IN THE GALLBLADDER AND BILE DUCTS. (Eng.) Hatfield, P. M.; Wise, R. E. (Lahey Clinic Foundation, 605 Commonwealth Ave., Boston, MA 02215). *Roentgenology* 11(3):157-164; 1976.

Information on the anatomic variations in the gallbladder and bile ducts is reviewed. The embryology of the gallbladder and extrahepatic ducts is discussed, together with the anatomic variations occurring in the gallbladder, cystic duct, extrahepatic ducts, and intrahepatic ducts. Agenesis of the gallbladder is of interest primarily because symptoms closely resembling those of cholecystitis may develop, even though the gallbladder is absent and the bile ducts appear entirely normal at surgery. If the peritoneal reflection that maintains the gallbladder in close apposition to the undersurface of the right liver lobe is lax or incomplete, a mobile or floating gallbladder may result, with intermittent herniation into the lesser sac through the foramen of Winslow. The partially or completely intrahepatic gallbladder greatly complicates cholecystectomy. Other anomalies of the gallbladder include suprahepatic, retrohepatic, and left-sided gallbladder, but these are rare. Cystic duct anomalies include completely separate insertion of the cystic duct into the duodenum; a duct that first passes anterior to the duodenum before coursing beneath it to insert into the common bile duct; and insertion of the cystic duct into the anterior or posterior margin of the common bile duct. Unlike the gallbladder and intrahepatic ducts, clinically significant anatomic variation in the extrahepatic ducts is uncommon and is usually the result of a generalized congenital aberration. Variation in the configuration of the ampulla of Vater and the point of junction of the pancreatic duct with the common bile duct is frequent and accounts for the often encountered difficulty in selecting the appropriate duct during retrograde p.o. cannulation. Large anomalous intrahepatic ducts that drain into the gallbladder occasionally occur; these may be severed at operation if unrecognized, resulting in persistent postoperative biliary fistula. The duct of the anterior or posterior segment of the right liver lobe may drain into the left rather than the right hepatic duct. Another common anomaly of the intrahepatic ducts is a low insertion of the right hepatic duct or of a segmental or subsegmental branch into the common hepatic duct. Meticulous cholangiographic examinations should reduce the occurrence of surgical injury due to the failure to recognize variations in biliary anatomy.

9048 DISEASES OF THE GALLBLADDER AND BILIARY PASSAGES. (Eng.) Small, D. M.; Bennett, P.; Carey, M.; Grundy, S.; Lester, R.; Palmer, R. (Work Group VI, American Gastroenterological Assoc.). *Gastroenterology* 69(5):1121-1130; 1975.

Research needs for diseases of the gallbladder and biliary passages are analyzed. Consideration is given to cholesterol gallstone disease, pigment gallstone disease, cholestasis in adults, diseases of the biliary tract in the newborn and infant, and miscellaneous diseases of the gallbladder and bilia tract. Epidemiologically, cholesterol gallstone disease is the most important, affecting 20-30 million Americans. Epidemiological studies are needed to answer a number of questions regarding etiology. Information is also needed on bile composition, the bile pool size, and synthetic and secretory rates of individual bile acids. New techniques needed include noninvasive methods for the diagnosis of potential gallstone formers, a method for quantitatively investigating gallbladder function in animal and noninvasive techniques for the quantitative determination of gallbladder contraction. This are is currently adequately funded. Epidemiological data on the incidence and prevalence of pigment stones are needed. Research in this area should receive increased support, not only because it affects 3-4 million Americans, but also because it appears that pigment stones may form the nucleus for cholesterol gallstone disease. Epidemiological and biochemical data relating to cholestasis in adults may be accomplished with existing methods, but more advanced studies than are currently in progress are needed. Among the needs in the area of fetal and neonatal biliary disease are tissue and organ culture of the fetal liver, intrauterine surgery, the use of stable isotopes in metabolic studies, noninvasive techniques, and applications of miniaturization developments. Specific information should be collected regarding fetal and neonatal bile salt metabolism, effects of developmenta changes and the intrauterine environment on fetal and postnatal hepatic function, neonatal cholestas and the relationships of neonatal nutrition and the liver. The importance of descriptive and epidemiological studies to define the nature of miscellaneous diseases of the gallbladder and biliary tract and of in-depth research on the quantitative function of the intact cholecystic duct and sphincter of Oddi in both animals and man is stressed.

9049 BIOCHEMICAL COMPOSITION OF THE BILE IN HEALTHY CHILDREN AND THOSE SUFFERING FRO DISEASES OF THE BILE TRACTS. (Rus.) Apostolov, B G.; Ivanov, A. I.; Kravchenko, L. I. (Leningrad In Hygiene and Medicine, Leningrad, USSR). *Vopr. Okh Materin. Det.* 21(5):47-51; 1976.

The biochemical characteristics of B and C biles were studied in 130 patients with chronic cholecys titis and in 17 healthy children. All children we aged 5-15 hr. The quantitative investigations revealed no difference in the bilirubin, choleste phospholipids, bile acids, lipid complex, hexoses, hexosamines, and the gallbladder concentration ind between the patients and the controls. The increa DNA level of the C bile in the patients was appare connected in some of the patients with concomitant duodenitis, duodenal stasis, and regurgitation of the intestinal content to the site of the catheter Involvement of the liver in the pathological proce was not observed. The complex clinical investiga-

ns, fractional duodenal catheterization, cholecys-
raphy, and biochemical investigations revealed
efly functional disturbances in the biliary tract
the patients.

0 INFLUENCE OF CERTAIN CHOLERETICS ON THE VOLUME AND COMPOSITION OF BILE IN HUMANS.

r.) Eulenburg, F.; Bode, J. Ch. (Medizinische
nik, Philipps-Universitat, Marburg, W. Germany).
Gastroenterol. 14(3):354-364; 1976.

effect of four commercial choleretic preparations
bile formation and composition is reported. The
t sample included eight patients, six of whom had
lecystolithiasis or choledocholithiasis with pre-
rative icterus, one with papillary stenosis, and
pancreatic pseudocyst with bile duct constriction.
lies were performed with T-drains in the ductus
ledochus (DC), 4-8 days after ductal revision.
test compounds, Cholagogum Nattermann (CN), Chol-
iz (CA), Chol-Kugelettes (CK), and Chologen 1
), were administered p.o. Fasting secretion was
3-0.93 ml/min; the average cholesterol excretion
420 μg/min, bilirubin was 196 μg/min, bicarbo-
e was 28 mEq/l, and calcium was 1.9 mEq/l. None
the test agents produced an unequivocal increase
bile volume. Bile acid secretion also was un-
ected. Although cholesterol excretion and bili-
in levels showed a wide variation in fasting,
ther of the levels was increased. Bicarbonate
assium, sodium, and calcium were unchanged. In
rast, after secretin the bile volume increased
average of fivefold within 30 min, and no patient
led to show less than a threefold rise. Bicarbo-
e concentration, total excretion, and cation ex-
tion also increased. Bile volume and bile acids
e 2.5-fold, and bilirubin fell to one-tenth the
ting secretion after dehydrocholic acid administra-
n. Taurocholic acid elevated the bile volume
e from 0.27 ml/min to 0.73 ml/min and the bile
d excretion from 2.2 μmol/min to 19.1 μmol/min,
bilirubin depression was slight. The findings
onstrate the inefficiency of the four choleretics
ted, because the changes they caused in choleresis
e within the physiological range.

1 BILE SALTS: THEIR ROLE IN CHOLESTEROL SYNTHESIS, SECRETION AND LITHOGENESIS.

.) Brandt, L. J.; Bernstein, L. H. (Montefiore
., 111 E. 210th St., Bronx, NY 10467). *Am. J.*
roenterol. 65(1):17-30; 1976.

physicochemical properties of bile salts and the
latory effects of bile salts on their own hepatic
thesis and on the hepatic and intestinal synthesis
cholesterol are reviewed. The dissolution of gall-
es using bile salts or phenobarbital is also dis-
sed. Bile salts represent the major products of
hepatic catabolism of cholesterol. Cholesterol
n obligatory precursor of the bile salts in all
ebrates studied. The rate at which the liver
hesizes cholesterol, bile acids, and cholesterol
hydroxylase (which catalyzes the first committed
of bile acid synthesis from cholesterol) appears
e controlled by the bile salt pool in a negative
lback fashion. Present evidence also suggests
that the cholesterol biosynthetic pathway is similar in the liver and the intestine. The evidence in man suggests that hepatic cholesterol synthesis is suppressed by cholesterol feeding, but that intestinal synthesis is not. Thus, during ingestion of a high cholesterol diet, the contribution of the intestine to the circulating endogenous cholesterol pool could equal or exceed that of the liver. Bile salts are conserved primarily by active reabsorption from the ileum, although the stomach, jejunum, and colon are capable of passive absorption; there are three possible mechanisms of bile salt absorption, i.e., active passive micellar, and passive monomeric. Following their absorption, bile acids are transported to the liver in the portal venous blood, bound primarily to albumin. Those bile salts that are not absorbed pass into the colon where they undergo a number of bacterially produced molecular changes resulting in the formation of secondary bile salts. The major physiological function of bile salts is to bring the products of pancreatic lipolysis (fatty acids and monoglycerides) into a micellar solution via their detergent properties. Most studies have indicated that the liver is responsible for the formation of lithogenic bile and that the gallbladder plays no significant role in altering the lipid composition of the hepatic bile. Although it is known that cholesterol will precipitate from bile if the ratio of bile salts and phospholipids to cholesterol falls below a critical level, the exact mechanism is unknown. The feeding of bile acids, particularly chenodeoxycholic acid, has been the most successful method of gallstone dissolution. Some studies have shown that the administration of phenobarbital reduces gallstone size. It can alter bile acid synthesis from cholesterol by altering the activity of cholesterol 7-α-hydroxylase. Future trials will determine whether substituting life-long therapy with bile acids for surgery is a worthwhile goal.

9052 CLINICAL PHARMACOLOGY OF CHOLECYSTOKININ AND PANCREOZYMIN.

(Rus.) Geller, L. I. (Khabarovsk Medical Inst., Khabarovsk, USSR). *Klin. Med. (Mosk.)* 54(3):23-29; 1976.

Results of investigations on the physiological effects of cholecystokininpancreozymin (CP) in normal subjects and in patients with gastroenterological diseases are presented. CP (1.5 U/kg, i.v.) caused a highly significant, but short-term (20 min), increase in the intraduodenal secretion of pancreatic enzymes both in normal subjects and in patients with duodenal ulcer and chronic recurrent pancreatitis. At the same time, an increase in the amylase/lipase coefficient and a decrease in the lipase/trypsin coefficient were observed. The relative reduction of the lipase level was considerably more pronounced in patients with chronic pancreatitis than in normal subjects. CP caused considerable contraction of the gallbladder, the appearance of B bile in the duodenum 3-4 min after administration, and prolonged secretion of C bile, suggesting the relaxing effect of CP on Oddi's sphincter. Investigations of the bilirubin and total lipid levels in C bile demonstrated the choleretic effect of CP. CP had an inhibitory action on gastric hydrochloric acid secretion in normal subjects and in patients with peptic ulcer, and it caused a marked inhibition of the gastroduodenal motor function.

9053 RENAL FUNCTION IN DISEASES OF THE LIVER AND BILIARY TRACTS. (Rus.) Furmanenko, E. D.; Potashnikova, N. P.; Driuk, O. N. (Kiev Scientific Res. Inst. Clinical and Experimental Surgery, Kiev, USSR). *Klin. Khir.* (6):14-16; 1976.

The functional status of the kidney was studied by radioisotope renography (^{131}I-labeled o-iodohippurate sodium) in 22 patients with chronic calculous cholecystitis, 15 patients with chronic noncalculous cholecystitis, and in 17 patients with liver cirrhosis. The changes in the renal function (reduction of blood clearance, delayed isotope accumulation and elimination, and reduced rate of isotope secretion) were smallest in patients with chronic noncalculous cholecystitis, more pronounced in patients with chronic calculous cholecystitis, and most pronounced in patients with liver cirrhosis. The functional changes were usually bilateral. The severity of the changes in the renal function correlated with that of the cholecystopathy and hepatopathy.

9054 A COMPARISON OF THREE CHOLECYSTOGRAPHIC AGENTS: A DOUBLE-BLIND STUDY WITH AND WITHOUT A PRIOR FATTY MEAL. (Eng.) Stanley, R. J.; Melson, G. L.; Cubillo, E.; Hesker, A. E. (Washington Univ. Sch. Medicine, 510 South Kingshighway, St. Louis, MO 63110). *Radiology* 112(2):513-517; 1974.

A double-blind technique was used in 726 patients to test three cholecystographic agents: iocetamic acid, iopanoic acid, and tyropanoate sodium. Standard prone and oblique radiographs plus erect spot films were obtained 10-15 hr after the patients ingested the agent. Graded scoring of radiographs, percentage of diagnostic first-day studies (either normal or diagnostic of abnormality and requiring no repeat study), and the incidence of adverse effects were evaluated. Among 405 patients who received a fat-free meal preceding the ingestion of one of the agents, a 4.5-g dose (6 x 750 mg tablets) of iocetamic acid produced the most dense shadows and highest diagnostic yield (76%), and iopanoic acid (3 g; 6 x 500 mg tablets) yielded the least dense shadows and lowest diagnostic yield (47%). A 3.0-g dose of iocetamic acid produced a 58% yield, and a 3.0-g dose of tyropanoate sodium produced a 71% yield. The difference in density between tyropanoate sodium and iocetamic acid (4.5 g) was not statistically significant. Among the 321 patients who received a fatty meal before ingesting the agent, diagnostic yields of 70, 65, 64, and 68% were obtained with iopanoic acid (3.0 g), iocetamic acid (3.0 g), tyropanoate sodium (3.0 g), and iocetamic acid (4.5 g), resp. The fatty meal also significantly increased the density of the shadows. For the respective agents and dosages, the percentages of patients given a fat-free meal who reported at least one side-effect (nausea and vomiting, diarrhea, headache) were 57, 53, 47, and 56%. Among the patients given a fatty meal, the corresponding percentages were 44, 48, 38, and 44%. Among 95 patients who receive a repeat p.o. dose of contrast medium, the percentages of reported side effects were 54, 44, 31, and 61%, resp. The incidence of diarrhea was greater in the patients given iopanoic acid than in the other agents in both the fatty meal and fat-free meal groups. The results show that significantly better gallbladder visualization was obtained in patients given a fat-free meal and the 4.5-g dose of iocetamic acid. The different effects of the fatty meal upon the various contrast agents suggest a dissimilarity in the properties of these agents relating to absorption and excretion.

9055 VALUE OF RETROGRADE ENDOSCOPIC CHOLANGIOPANCREATOGRAPHY IN CASES OF NEGATIVE OR NON-EVALUABLE CHOLECYSTOCHOLANGIOGRAM. (Ger.) Deyhle, P.; Stuby, K.; Jenny, S.; Nuesch, H. J.; Kobler, E.; Ammann, R.; Sauberli, H. (Departement fur Innere Medizin, Kantonsspital, Ramistrasse 100, CH-8091 Zurich, Switzerland). *Schweiz. Med. Wochenschr.* 106(9):314-315; 1976.

The indications for endoscopic retrograde cholangiopancreatography (ERCP) are summarized, and experiences with 299 patients in whom i.v. cholecystograp or cholangiography was negative, not evaluable, or not possible are presented. In 45 cholestatic patients, gallstones were identified in 11, extrahepatic duct malformation in 3, papillitis in 3, chronic pancreatitis in 2, pancreatic cyst in 2, tumor adjacent to the liver hilus in 2, and pancreatic carcinoma in 5; 17 patients were negative. The ERCP findings in icterus determine the surgical approach, for which the clarification of extrahepatic and intrahepatic localizations is especially useful. In 37 patients with nonspecific epigastric problems, ERCP found stones in 3, papillitis in 1, ductal malformation in 1, and pancreatic carcinoma in 3; 29 patients were negative. In 55 postcholecystectomy syndromes, stones were identified in 9, papillitis in 7, ductal malformation in 1, pancreatitis in 1, and tumor adjacent to the liver hilus in 2; 35 patients were negative. Only seven instances of complication were established: 5 pancreatites and 2 cholangites, with cyst or tumor cavity filling. ERCP is the method of choice in obstructive jaundice and unclarified cholestasis.

9056 PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY (Eng.) Lang, E. K. (Louisiana State Univ Sch. Medicine, Shreveport, LA 71101). *Radiology* 112(2):283-290; 1974.

Percutaneous transhepatic cholangiography was used in the diagnosis of 112 patients with obstructive jaundice. A highly flexible 18-20 gauge polyethylene catheter was advanced 15-18 cm into the liver parenchyma, and bile was aspirated for 10-20 min. Then 10-18 ml of contrast material was infused, and anteroposterior, oblique, and cross-table lateral projections were used to visualize the site of obstruction. This technique is contraindicated in patients with hemorrhagic diathesis,

t responding to medication and in those with
spected *Echinococcus* infection and/or echinococcal
sts. In the present series, percutaneous trans-
patic cholangiography permitted accurate diagnosis
63 of 66 patients (95%) with obstructive jaundice
sulting from calculi in the common duct and those
th carcinoma of the head of the pancreas, papilla
Vater, common duct, or gallbladder. This tech-
que was also reliable for assessing recurrent
oplasms obstructing the choledochojejunostomy
llowing Whipple's procedure. Successful diagnosis
s obtained in only 57% of the patients with
ronic pancreatitis. Puncture was successful in
ly 3 of 10 patients with hepatitis. In patients
th primary or secondary neoplasms of the liver,
rcutaneous transhepatic cholangiography merely
dicated that a space-occupying lesion was present;
teriography or nuclear imaging was required for
definitive diagnosis. In five patients, retention
the Teflon tubing introduced during the puncture
create a temporary or semipermanent biliary
stula was of therapeutic benefit in alleviating
ritus, improving the general condition of the
tient, and permitting earlier surgical interven-
on, or in palliation of terminal disease. A
nplication rate of 10% was recorded; complications
cluded two mild cases of bile peritonitis, five
lerate i.p. hematomas, and one death attributed
gram-negative septicemia.

7 REOPERATIONS FOLLOWING CHOLECYSTOSTOMY.

(Rus.) Nechay, A. I. (Surgical Clinic,
M. Kirov Military Medical Acad., Leningrad, USSR).
rurgiia (10):36-40; 1975.

26 patients subjected to cholecystostomy, 15
h external biliary fistula and 4 with mucous-
prative fistula were admitted to hospital for
peration. At the second operation, malignant tumor
the pancreas was found in two patients and adeno-
cinoma of the major duodenal papilla was found
one. All three patients died. Twelve patients
calculus in the common bile duct and in the gall-
dder, and one had stenosing papillitis. Ten pa-
nts showed no pathological changes in the bilio-
creatic system. Reoperations included removal
the gallbladder in all but one patient. In addi-
n to the cholecystostomy, 15 patients were sub-
ted to choledochotomy. Of the 23 patients who
vived surgery, one, an 82-yr-old woman, died on
2 of acute cardiac insufficiency and the other,
8-yr-old woman, died 32 days postoperatively of
creanecrosis.

8 TREATMENT OF BILIARY ATRESIA. (Eng.)

Bill, A. H. (Children's Orthopedic Hosp.
Medical Center, Seattle, WA). *Adv. Surg.* 8:63-
1974.

pathology and treatment of biliary atresia are
iewed. New information on the pathology of the
er demonstrates that biliary atresia has features
common with neonatal hepatitis. The peripheral
ll drainage ducts may be obstructed early,
ding to cirrhosis; the major intrahepatic ducts may be open to the porta hepatis in the first several months of the disease; and the closure of the extrahepatic ducts may be due to some form of cholangitis. For successful surgical treatment, the diagnosis must be made before 90 days of age and, preferably, before 70 days of age. Diagnosis rests on the presence of relatively acholic stools, a needle biopsy of the liver, and repeated scans showing abnormal retention of ^{131}I-rose bengal dye in the liver. Inspection of the gallbladder and surgical cholangiogram under local anesthesia may also be necessary. The operation devised by Kasai is used in the 90% of patients who have no segment of the extrahepatic duct that can be anastomosed to the intestine. This operation consists of a shallow excision of tissue at the porta hepatis, followed by anastomosis of the small bowel around this area. To prevent the otherwise frequent and often fatal ascending cholangitis, Kasai and his colleagues recommend anastomosis to small intestine with a decompressing external vent. A 40% survival without jaundice for 1 yr or more has been reported when this operation is done before 90 days of age; after 90 days, this survival drops to 7%. These results have improved when surgery was performed before 70 days of age.

9059 STUDIES OF "BLACK BILIARY CALCULI" (EXISTENCE OF MELANIN-LIKE CALCULI). (Eng.)

Nagamitsu, S. (First Dept. Surgery, Faculty Medicine, Kyushu Univ., Fukuoka, Japan). *Gastroenterol. Jpn.* 9(4):359-368; 1974.

Chemical analyses were made of calculi from 24 patients with "black biliary calculi," 22 with cholecystolithiasis, and 2 with choledochocholecystolithiasis. The black biliary calculi are more rapidly discolored by hydrogen peroxide than the brown bilirubin calculi and are assumed to be melanin-like substances. Six of the patients had 1 calculus, 10 had 2 to 100 calculi, and 7 had 100 or more. Macroscopic and histopathological examinations showed that 17 of them had mild or no lesions in the gallbladder, 6 had moderate ones, and 1 had a severe lesion. Lesions in the gallbladder of seven black biliary calculi patients were complicated by strawberry gallbladder, a finding that is rare in bilirubin calculi patients. A metabolic etiology should be considered for the formation of black biliary calculi. Five of these patients showed abnormal findings in liver function tests. Histopathological examinations revealed cirrhosis of the liver in three patients and mild fatty infiltration in two. No pigmentation in the hepatocytes was found. Nineteen of the patients showed positive roentgenograms. Cu, Fe, and Ca are abundant in black biliary calculi, which supports the idea that the black pigment is a melanin-like substance. The calculi may stay in the gallbladder for a long period, bind Ca and other metabolic components to increase their quantity, and eventually give a positive roentgenogram.

9060 POSTOPERATIVE CHOLANGIOLITHIASIS. (Rus.)

Danilov, M. V.; Shishka, K. (A.V. Vishnevskii Inst. Surgery, USSR Acad. Medical Sciences, USSR). *Klin. Khir.* (6):6-10; 1976.

Seventy-six cases of postoperative cholelithiasis occurring after cholecystectomy are presented. Cholangiolithiasis was the only lesion of the bile ducts in 43 cases, and it was due to cholestasis or parasitic invasion, with onset before or after the primary surgery in 33 cases. The incidence of residual calculi at the primary surgery for cholelithiasis can be reduced by careful inspection, cholangiography, and cholangioscopy during cholecystectomy. If multiple calculi are not removed completely and with certainty, wide biliodigestive anastomosis is recommended. Bloodless removal of residual calculi during the postoperative period is possible by means of Dormia's loop under x-ray control. Reoperation for residual or recurrent calculi 1.5 months or more after the first intervention requires internal drainage of the biliary tract.

9061 A STUDY OF TRANSAMINASE ACTIVITY IN LITHIASIC AND CANCEROUS EXTRAHEPATIC BILIARY TRACT OBSTRUCTION.

(Fre.) Tete, R.; Rouchier, D.; Teulieres, J. P.; Vachon, A. (Hotel-Dieu, 1, place de l' Hopital, F 69288 Lyon Cedex 1, France). *Lyon Med.* 233(4):369-379; 1975.

Transaminase (TR) behavior in extrahepatic biliary obstructive pathology was compiled and correlated with disease states. The clinical sample included 82 cases of lithiasis, 75 carcinomas of the head of the pancreas, and 1 bile duct carcinoma. Elevated TR levels were found in 43 of 82 patients with common duct lithiasis; 9 of the 43 had elevated SGPT and SGOT levels (300 Frankel units/ml; normal, 45 FU/ml). The maximum was reached 7 days after the onset of pain and fever and 5 days after icterus. There was no correlation between symptom complex and the number of normal or elevated TR levels. The SGOT/alkaline phosphatase (AP) quotient, corrected for unit conversion, was >10 in six cases, >7 in eight, between 3 and 7 in five, and <3 in none. Among the pancreatic carcinoma patients 47 of 75 had increased TR, with eight SGPT and seven SGOT levels >300. The maximum appeared 19.5 days after icterus. Comparison of symtomatology and TR found normal levels in 21 of 28 with icterus, in 1 of 28 with icterus and fever, and in 6 of 28 with icterus and pain; elevated levels were observed in 41 of 47 with icterus, 2 of 47 with icterus and fever, and 4 of 47 with icterus and pain. The SGOT/AP quotient was >10 in four cases, >7 in eight, between 3 and 7 in nine, and <3 in three. The SGPT/AP was >10 in 5, >7 in 10, between 3 and 7 in 1, and <3 in 4. In the two bile duct carcinomas, the patient with hilar involvement had SGOT, 550; SGPT, 1000; SGOT/AP, 4.6; and SGPT/AP, 6.6. The patient with localization at the ampulla of Vater had SGOT, 140; SGPT, 200; SGOT/AP, 21; and SGPT/AP, 39. In all, 92/159 had elevated SGOT or SGPT; the mean values for SGOT and SGPT, resp., were 170 and 196. There was no difference in TR behavior in lithiasis or cancer, although more moderate increases (100-200 FU) were detected in lithiasis. The relation between stasis and hepatocyte injury is reviewed.

9062 ROLE OF BILE MICROFLORA IN THE ETIOLOGY AND PATHOGENESIS OF CHOLECYSTITIS.

(Rus.) Karavanov, G. G.; Rachkevich, S. L. (Lvov Medical Inst., Lvov, USSR). *Klin. Khir.* (6):10-13; 1976.

Bile samples obtained aseptically during operation or by transcutaneous-transhepatic biopsy from 125 patients with various diseases of the gallbladder and biliary tracts were investigated for infection with microorganisms. Eighty strains of microorganisms were found in 65 patients. Single species wer found in 50 cases and associations of strains in 15. The incidences were 35 of 80 for *Escherichia coli*, 2 of 80 for *Staphylococcus*, 6 of 80 for *Klebsiella*, 7 80 for *Enterococcus*, 2 of 80 for *Candida*, 2 of 80 fo *Salmonella typhosa*, 1 of 80 for *Proteus*, and 3 of 80 for other saprophytes. The incidences of positive bile samples were 15/38 in chronic cholecystitis, 13/18 in aggravated chronic cholecystitis, 26/36 in destructive cholecystitis, 0/10 in bile duct obstruction, 2/11 in cholesterosis, 8/10 in postcholecystectomy syndrome, and 1/2 in other biliary pathologies. The incidence of positive samples was 24/71 in patie without pathological changes of the common bile duct 15/22 in choledocholithiasis, 7/9 in stenosis of the ampula of Vater, 10/12 in pancreatitis, and 9/11 in cholangitis. The findings indicate that while infection is not the prime cause of cholecystitis, it pla an important role in the pathogenesis of this diseas

9063 PAPILLOSPHINCTEROTOMY IN SURGERY FOR COMPLICATED CHOLECYSTITIS.

(Rus.) Knubovets S. Y.; Novikov, F. V.; Zaripov, R. A. (A. V. Vishnevskii Clinic Surgery, Kazan Medical Inst., Kazan, USSR). *Khirurgiia* (10):29-33; 1975.

Experience with papillosphincterotomy in surgery for acute cholecystitis is reviewed. Of 738 patients with complicated cholecystitis treated surgically during 1960-1972, 75 underwent surgery on the major duodenal papilla. After papillosphincterotomy, 57 patients developed jaundice, 40 developed cholangitis, 23 had calculi in the common bile and hepatic ductus, 31 had calculi in the common bile and hepatic ductus and in the duodenum papilla, and 14 had calculi only in the duodenum papilla. Papillosphincterotomy was the treatment of choice when the diameter of the common bile duct was less than 15 mm Two patients underwent papillotomy; 31, partial papillosphincterotomy; 36, subtotal papillosphincterotomy; and 6, total papillosphincterotomy. Five patients underwent additional supraduodenal choledochoduodenostomy. Immediately after surgery, three patients died (one each of double pneumonia, pancreonecrosis, and choledochoduodenostomosis failure). Forty-one patients were followed up for 2-10 yr: 37 were in good condition, and 4 were in satisfactor condition.

9064 DIFFERENTIAL DIAGNOSIS OF DYSKINESIA OF TH BILE TRACTS IN CHILDREN AND TACTICS USED IN THE TREATMENT.

(Rus.) Druzhinina, E. I.; Khodunova, A. M. (Ivanovo Medical Inst., Ivanovo, USSR). *Vopr. Okhr. Materin. Det.* 21(5):51-55; 1976.

The differential diagnosis of dyskinesia of the bili ry tract in 96, mainly school-aged children is described. Dyskinesia was associated with cholangitis in 41 cases. Fractional duodenal catheterization by means of a double-canal catheter with graphic displa of the data and intravenous cholangiography with lculation of the index of the gallbladder motor nction proved to be most valuable for the diagnosis. pertonic dyskinesia was diagnosed in 49 cases, the perkinetic form in 28, and hypotonic dyskinesia 12; the type of dyskinesia could not be established th certainty in 7 cases. There was no correlation tween the type of the pains and the type of dyskin- a. The time elapsing until the appearance of B e after cholagogue administration averaged 27 in hypertonic dyskinesia, 3.5 min in the hyper- etic form, 7 min in the hypotonic form, and 12 in indefinite dyskinesia. The volumes of the e secreted were 18.5, 11.5, 59.4, and 42 ml, resp. e duration of B bile secretion was 37, 13, 26, 19 min. Patients with hypertonic dyskinesia ceived spasmolytics and choleretics. Patients th hypotonic dyskinesia were treated with stimu- ats, magnesium sulfate, and sorbitol.

55 ULTRASONIC STUDY OF VENOUS PATTERNS IN THE RIGHT HYPOCHONDRIUM: AN ANATOMICAL PROACH TO DIFFERENTIAL DIAGNOSIS OF OBSTRUCTIVE UNDICE.

(Eng.) Weill, F.; Eisenscher, A.; Aucant, ; Bourgoin, A.; Gallinet, D. (Service central de diologie, Departement de diagnostic, 2 Place St. cques, 25000-Besancon, France). *J. Clin. Ul- asound* 3(1):23-28; 1975.

e identification of intrahepatic portal veins, stemic veins, and biliary ducts by real-time ultra- nic scans and their use in the differential diag- sis of obstructive jaundice are discussed. The perior mesenteric vein can be identified during first aortic scan or by alternate right and left vements of the ultrasonic head. Its confluence th the vena porta is then sought, and the latter followed from the confluence zone of the hilus. rpendicular transverse scans are then performed examine the hilar portal veins. Transverse abdom- al scans, alternately caudad and cephalad, permit sualization of the splenic vein, after which alter- te left-right movements can be used to follow it. jaundice, the presence or absence of confluence an oblique tubular structure with the superior senteric vein and splenic vein in the right hypo- ondrium is the most reliable means of differentia- g an enlarged common bile duct from the vena porta. terior oblique recurrent retrocostal scans of the ver, with movements of the ultrasonic head parallel the skin surface, display a ductal network in the lum area, and scans of the portal vein usually ow the confluence of this network with the portal in. The confluence of this network with the vena va can also be demonstrated clearly. Demonstra- on of such confluence is necessary to distinguish rtal enlargement caused by portal hypertension, stemic venous enlargement caused by cardiac insuf- ciency, and nonpathological wide veins from obs- uctive jaundice. In the jaundiced patient with enlarged common bile duct, it will be possible demonstrate a confluence between enlarged hilar le ducts and the common bile duct.

56 THE HYPERCHOLESTEROLAEMIA OF OBSTRUCTIVE JAUNDICE.

(Eng.) McIntyre, N.; Harry, D. ; Pearson, A. J. G. (Royal Free Hosp., Pond St., ndon, England). *Gut* 16(5):379-391; 1975.

Recent information concerning the hypercholesterolemia of obstructive jaundice is reviewed. Lipoprotein-X (LP-X), changes in other lipoproteins in obstructive jaundice, the accumulation of cholesterol in plasma, and the clinical importance of high free cholesterol levels are discussed. After the removal of normal low-density lipoprotein from the low-density fraction of patients with obstructive jaundice using antibodies to normal lipoprotein, LP-X remains; this lipoprotein is rich in phospholipid, and 96-100% of the cholesterol is unesterified. Electron microscopy of LP-X has revealed the presence of discs, which are probably flattened vesicles. Cholesterol synthesis in rat liver has been found to be strikingly increased following the ligation of the common bile duct, and this has been accepted as an explanation of the hypercholesterolemia of obstructive jaundice. An altered liver-plasma cholesterol partition also appears to be involved. The mechanism of increased hepatic cholesterol synthesis in obstructive jaundice is not yet clear. A hypothesis concerning biliary lecithin is the most satisfactory explanation available for the hypercholesterolemia of obstructive jaundice. The evidence suggests that lecithin cholesterol acyl transferase, which acts in plasma, is largely responsible for the production of plasma cholesteryl esters. For acyl transfer to occur, free cholesterol and lecithin must enter the plasma, and these compounds should accumulate if lecithin cholesterol acyl transferase activity is reduced; such changes have been found to occur with familial deficiency of lecithin cholesterol acyl transferase and with biliary obstruction. Lecithin cholesterol acyl transferase deficiency may play a part in hypercholesterolemia and may account for lipoprotein changes other than the appearance of LP-X (i.e., changes in high-, low-, and very low-density lipoproteins) in hypercholesterolemia, as some of these changes have been shown to be reversed by the action of the enzyme. Hypercholesterolemia has been produced by the i.v. injection of lecithin in cholecystectomized dogs with common bile duct obstruction. The most striking clinical consequence of hypercholesterolemia is cutaneous xanthomata. Hypercholesterolemia can also cause problems in the interpretation of some laboratory tests, such as lipoprotein electrophoresis for the typing of hyperlipidemia and the measurement of antistreptolysin O titer. Because steroid treatment has been unsuccessful in reducing plasma cholesterol in obstructive jaundice, mechanical methods have been tried. Although plasmaphoresis and plasma exchange are time consuming and inconvenient for the patient, they are effective in reducing plasma cholesterol and in causing the regression of xanthomata.

9067 PATHOGENESIS OF HYPERLIPIDEMIA IN BILIARY OBSTRUCTION.

(Eng.) Osuga, T.; Oda, T. (First Dept. Internal Medicine, Faculty Medicine, Univ. Tokyo, Tokyo, Japan). *Jpn. J. Med.* 14(2): 110-114; 1975.

The pathogenesis of the plasma lipid increment in biliary obstruction was studied with particular reference to the transport and metabolism of cholesterol, lecithin, and bile acids. Diverting bile flow in the squirrel monkey caused rapid changes in the lipid composition. Total and individual bile acids and lecithin concentration in the hepatic bile dropped rapidly. Cholesterol concentration dropped to a lesser extent and even increased in some cases. In several monkeys to whom ^{14}C-cholic and ^{14}C-chenodeoxycholic acid were given i.v. prior to diversion, the specific activity of the individual bile acids in the hepatic bile decreased after ligation, showing that the synthesis of bile acid was renewed in response to interruption of the enterohepatic circulation (EHC). In cases of biliary diversion, the molar percent of cholesterol in the bile increased with time, in contrast to the bile acid. Thus, the renewed synthesis of cholesterol exceeded that of bile acid stimulated by EHC interruption. In dogs in whom the bile ducts were ligated and T tubes inserted to monitor and compare the changes in biliary lipids, the plasma and biliary lipid contents were reversed. In plasma, the cholesterol, lecithin, and bile acids increased 24 hr after ligation, whereas they decreased in the bile. Although regurgitation of bile lecithin into plasma in cases of obstruction was not noted, palmitate was dominant in plasma, bile, and liver after bile duct ligation, and it was dominant in bile prior to ligation. Bile acids and lecithin changed almost concomitantly in plasma and bile in most cases, such as bile diversion or bile duct ligation, implying the close relation between them. In acute biliary obstruction, plasma LCAT activity was elevated with an increment of free and esterified cholesterol in plasma. In the chronic stage with liver cell damages, however, LCAT was reduced and the ratio of esterified to total cholesterol declined.

GENERAL

3 MICROCIRCULATORY CHANGES IN THE GASTROINTESTINAL TRACT OF THE HYPOXIC PUPPY: AN CTRON MICROSCOPE STUDY. (Eng.) Harrison, M. W.; nel, R. S.; Campbell, J. R.; Webb, M. C. (Dept. rgery, Univ. Oregon Health Sciences Center, 3181 . Sam Jackson Park Road, Portland, OR 97201). *Pediatr. Surg.* 10(5):599-608; 1975.

gain insight into the development of necrotizing terocolitis of the newborn, the early histologic l ultrastructural changes in the gastrointestinal ct of the hypoxic puppy were studied. Hypoxia s induced in four puppies by increasing the flow N_2 into an endotracheal tube until the O_2 concentration was 7%; the animals were maintained under these conditions for 2 hr before sacrifice. Hypovolemia was induced in four other puppies by withdrawing one-half of the estimated blood volume; the animals were killed 1 hr later. PaO_2 was lower in the hypoxic puppies than in the hypovolemic or control puppies, but the three groups did not differ in terms of heart rate, systolic blood pressure, central venous pressure, pH, or $PaCO_2$. The ileum and, to a lesser extent, the jejunum were cyanotic in the hypoxic animals; the vasculature was prominent, but pulsations were reduced as in the hypovolemic animals. Both groups also demonstrated pale viscera. Light microscopy revealed only minor differences among the control, hypovolemic, and hypoxic puppies. Electron microscopy showed similar changes in the hypoxic and hypovolemic animals, particularly in the ileum and colon. There was an aggregation of platelets and WBC in the vascular space, focal endothelial cell disruption, increased amounts of perivascular edema, and a loss of ultrastructural organization in the mucosal cells. These changes, which were not seen in the controls, appeared to relate to variations in the blood flow to the mucosa of different areas of the bowel and to follow the distribution observed for necrotizing enterocolitis in the human infant.

9094 HISTOLOGIC APPEARANCE OF THE INTESTINAL URINARY CONDUIT. (Eng.) Garner, J. W.; Goldstein, A. M. B.; Cosgrove, M. D. (Los Angeles County—Univ. Southern California Medical Center, Los Angeles, CA). *J. Urol.* 114(6):854-857; 1975.

To identify any adaptive changes that may occur in the intestine when it functions as a conduit of urine, the histology of intestinal urinary conduits (8 ileal and 2 sigmoid) in place for 10 months to 10 yr was studied in 10 patients. The patients were 20-65 yr old. The mucosa of all the ileal conduits displayed chronic inflammatory changes. Mild mucosal edema was found in nine cases, and shortening, flattening, or absence of villi occurred in four patients. The striated border was well preserved, but of patchy distribution in six of the eight ileal conduits. No chronic inflammatory changes of the mucosa of the two sigmoid conduits were found. In both the sigmoid and the ileal conduits, the surface epithelial cells and the lining epithelium of the crypts, including the goblet cells, were well preserved. In all cases, the cells of Paneth were well developed and numerous, even when the conduit was in place for 10 yr. Electron microscopy demonstrated that the Paneth cells were completely normal. It is concluded that the ileum and the large intestine do not undergo adaptive metaplastic transformation when used as a conduit of urine.

9095 HUMAN FAECAL IMMUNOGLOBULINS IN HEALTHY INFANTS AND CHILDREN, AND IN SOME WITH DISEASES AFFECTING THE INTESTINAL TRACT OR THE IMMUNE SYSTEM. (Eng.) Haneberg, B.; Aarskog, D. (Barneklinikken, Haukeland sykehus, N-5016 Bergen, Norway). *Clin. Exp. Immunol.* 22(2):210-222; 1975.

The value of fecal material for studying intestinal immunoglobulins was investigated by comparing the fecal immunoglobulins in 161 healthy infants and children to those in patients with diseases of the intestinal tract or the immune system. The presence of immunoglobulin A (IgA), IgG, and IgM in feces was quantified by single radial immunodiffusion using extracts of freeze-dried feces. IgA in small specimens of feces seemed to mirror the total amount of IgA secreted into the gut at the time of sampling. Presumptive normal values for fecal IgA concentrations in infants and children were established. Agglutinins to rabbit RBC served as markers for the antibody activity. Feces from 17 infants and children just recovered from infectiou enteritis contained significantly higher ($p<0.001$) levels of IgA than feces from controls. IgG was found in feces from nearly one-third of the patien whereas in the controls aged 1 month or older, IgG was measurable in only 4 of 138. The serum levels of IgA and the agglutination titers in the patient group did not differ from the controls. Feces fro three out of five patients with ulcerative colitis in remission contained IgG in markedly increased concentrations. Two patients with IgA deficiency had no detectable IgA in feces, but had increased levels of fecal IgM that agglutinated rabbit RBC. Immunoglobulins were not demonstrated in feces fro three patients with agammaglobulinemia. The findings indicate that feces can be used for the assay of intestinal immunoglobulins.

9096 PROSTAGLANDINS AND CHOLERA: THE OCCURRENCE OF PROSTAGLANDIN-LIKE SMOOTH MUSCL CONTRACTING SUBSTANCES IN CHOLERA DIARRHOEA. (Eng Okpako, D. T. (Dept. Pharmacology, Univ. Ibadan, Ibadan, Nigeria). *Prostaglandins* 10(5):769-777; 1975.

Prostaglandin-like substances (PLS) that contracte smooth muscle were identified in the acid lipid extracts of diarrheal feces from 10 of 11 patients presenting clinical symptoms of cholera. Five of these cases were subsequently confirmed bacteriologically, while no *Vibrio cholerae* were isolated from the cultures of the other six. The PLS activity in individual samples ranged from 3 to 27 ng of prostaglandin E_2 (PGE_2) equivalents per ml of stool. Parallel bioassay (with either the rat stomach strip or the rat stomach and rat colon) an thin layer chromatography indicated that approximately 60% of the activity was due to PGF, 15% to PGE, and the rest to unidentified lipid substance(It is suggested that increased prostaglandin production may at least contribute to cholera.

9097 INFANTILE PAPULAR ACRODERMATITIS: A REVIEW OF THREE CASES. (Fre.) Laurent, Caperan, D.; Esgavoyer, J.-M.; Agache, P.; Raffi, (Clinique Pediatrique, C.H.U., 25000 Besancon, France). *Rev. Pediatr. (Paris)* 11(6):315-319; 197

Three case histories of pediatric papular acroderma titis (PA) are described. Each child presented wi a characteristic picture of reddish, often purpura lenticular papules, especially on the cheeks and limbs. Pruritis was rare, but the eruption was regularly associated with micropolyadenopathy and discrete hepatomegaly; splenomegaly was less frequent, and fever and rhinopharyngitis were transient. The onset of PA is routinely sudden, withi 24-48 hr, and it remains unchanged for 20-40 days before diminishing after a brief desquamation phas The hematology is nonspecific: lymphocytosis is constant and it can persist for 4 months, but the monocytosis is transient. Ganglion histopathology shows a diffuse reticulohistiocytic hyperplasia. In the three children, the transaminases were norm at onset of eruption and increased slightly and

:ansiently, especially SGOT; serum LDH and aldolase
ere also elevated. The presence of the Australia
ıtigen in all three cases suggests that there may
: an etiologic relation to serum hepatitis.

)98 TRANSCATHETER HEMOSTASIS OF GASTROINTESTINAL BLEEDING USING MODIFIED AUTOGENOUS
.OT. (Eng.) Bookstein, J. J.; Chlosta, E. M.;
oley, D.; Walter, J. F. (Univ. Hosp., 225 Dicken-
on St., San Diego, CA 92103). *Radiology* 113(2):
77-285; 1974.

:eliminary experiments were carried out in six
ogs and nine humans to evaluate the use of modified
ıtogenous clot as an agent for transcatheter hemos-
ısis. The renal arteries of the dogs were cathe-
erized. Sixteen embolic aliquots were injected
ıto the dogs' kidneys, using modified and unmodified
.ots, i.e., an unmodified clot formed from 5 ml of
.ood allowed to set for 15-60 min, a clot consisting
: 0.24 or 12.5% amino caproic acid, a clot formed
ı a matrix of oxidized cellulose, and a clot con-
ıining both amino caproic acid and oxidized cellu-
ose. Appropriate aliquots of clot, usually 0.1 ml
: oxidized cellulose clot or 0.5-1 ml for other
.ots, were injected. Arteriograms were obtained
:ior to, approximately 2 min after, and usually
5 min and 24 hr after embolization. Unmodified
.ot fragmented and lysed extremely rapidly and left
) significant infarction in the four injected
.dneys. The 0.24% amino caproic acid containing
.ot behaved as an unmodified clot in three injected
.dneys. The 12.5% amino caproic acid clot (1 ml)
ostructed larger arteries than the unmodified clot,
ıd produced a few small infarcts in the two injected
dneys. An oxidized cellulose clot of 0.1 ml
oduced obstruction of larger arteries in the four
dneys injected than 1 ml of amino caproic acid
ot, and extensive infarcts were produced. The
havior of a single clot formed from both oxidized
llulose and amino caproic acid in a single dog
s similar to that of a clot formed from oxidized
llulose alone. Gastrointestinal bleeding was
eated by transcatheter clot embolization in nine
tients, six of whom had been previously treated
th vasopressin but did not respond. Depending
on the clinical and coagulation conditions, the
llowing agents were added: 300 NIH U thrombin;
ino caproic acid consisting of 0.5% of the clot;
osened oxidized cellulose; and 1 ml of platelets.
e total volume of clot was 1.0-2 ml. Bleeding
s immediately controlled in all patients, and
ntrol was permanent in seven. Among the five
rviving patients, there were two instances of
ansient duodenal infarction. Transcatheter
bolization should be used in cases in which vaso-
essin has failed to control gastrointestinal
morrhage. Care must be taken to use the smallest
ssible amount of clot and to position the catheter
p as close to the bleeding site as possible.

99 SHIGELLOSIS SIMULATING SERIOUS HEMORRHAGIC RECTOCOLITIS. RADIOLOGICALLY MANIFEST
LIC ULCERATIONS; DIAGNOSTIC PROBLEMS. (Fre.) Weissman, A.; Preel, J.-L.; Blanc, D.; Boussougant, Y.; Hardouin, J.-P. (Hopital Louis-Mourier, F 927000 Colombes, France). *Ann. Med. Interne (Paris)* 127(3):269-273; 1976.

Problems in the differential diagnosis of shigellosis are examined in a case report. A 63-yr-old woman with no gastrointestinal history presented with massive diarrhea, nausea, vomiting, and fever after a visit to the tropics. Treatment with diphenoxylate was ineffective. The patient became increasingly dehydrated, with marked leukocytosis and 78% neutrophilia. Coproculture was negative. Colistine, paromomycin, and metronidazole were without result. Rectoscopy showed a hemorrhagic and purulent mucosa, and biopsy revealed a nonspecific picture of necrosis, ulceration, and an excess of neutrophils, lymphocytes, and plasmocytes. The diagnosis was hemorrhagic rectocolitis after colon intolerance of barium lavage. The signs and symptoms were subsequently rapidly exacerbated, with paraclinical confirmation of acute exudative colopathy: calcium, 78 mg/l; magnesium, 13 mg/l; albumin, 22 g/l; protein, 44 g/l; lipid, 4.3 g/l; and cholesterol, 0.9 g/l. A fecal culture disclosed the presence of *Shigella dysenteriae*. The serum was then found positive (1 of 100) for *S. dysenteriae* and *S. flexneri* I, but not *S. sonnei*. Cure was rapid with ampicillin (6 g/l, i.v.) and colistine (3 x 10^6 U/daily, p.o.), and there was complete clinical and paraclinical normalization in 2 months.

9143 SYNDROMES IN AMOEBIC LIVER ABSCESS. (Eng.) Ramachandran, S.; Goonatillake, H. D.; Induruwa, P. A. C. (Colombo North General Hosp., Ragama, Sri Lanka). *Br. J. Surg.* 63(3):220-225 1976.

The syndromes found in amebic liver abscess are discussed in relation to right and left lobe abscesses, and the chronological sequence in the evolution of the diverse syndromes is presented. Observations were made on 137 patients, most of whom presented with classic syndromes of fever, right abdominal or chest pain, hepatomegaly, hepatic tenderness, and radiological abnormalities. Other syndromes of presentation included the silent abscess, acute amebic colitis, the acute abdomen, the intra-abdominal lump, the external sinus, pyrexia of obscure origin, obstructive jaundice, and renal, pleuropulmonary, and cardiac symptoms. Certain features developing against a background of the classic syndrome nearly always indicate the presence of an abscess of appreciable dimensions. These features include slowly or rapidly increasing hepatomegaly, increasing hepatic tenderness in spite of amebicidal therapy, formation of a lump with or without pointing, major pleuropulmonary or pericardial involvement, obstructive jaundice, and abdominal manifestations suggestive of prerupture or intraperitoneal rupture. Diagnostic difficulties arise when the typical features of the classic syndrome are inconspicuous, absent, or occur late in the course of the illness. Syndromes due to an abscess in different parts of the right and left lobes of the liver are to some extent distinct. Understanding the chronological sequence of the disease and its progression from one syndrome to another are important for a correct diagnosis.

Regional Enteritis

9174 THE PLACE OF ILEORECTAL ANASTOMOSIS IN CROHN'S DISEASE. (Eng.) Steinberg, D. M.; Allan, R. N.; Cooke, W. T.; Alexander-Williams, J. (4 Ventnor Ave., West Perth, Western Australia 6005). *Aust. N.Z. J. Surg.* 46(1):49-54; 1976.

A long-term follow-up study was performed on 41 patients having undergone an ileorectal anastomosis after colectomy for Crohn's disease. One patient died, an operative mortality of 2.5%, and nine of the patients had evidence of an anastomosis leak. Six had a defunctioning ileostomy at the time of the surgery. Seven have since died, a late mortality of 17.5%; three deaths were a direct consequence of recurrent disease. Profuse diarrhea, uncontrolable by steroids or antidiarrheal agents, was the major factor leading to a decision to substitute an ileorectal anastomosis for an ileostomy. Proven recurrent disease was found in 20 of the 36 patients having a follow-up period of at least 7 yr. In all 20, the recurrence was adjacent to the anastomosis. The current health status, biochemical and hematological parameters, and the number of reoperations in the surviving patients compare favorably with the outcome of 64 patients surviving ileostomy. Patients who maintained their ileorectal anastomosis had relatively few readmissions to the hospital. A higher incidence of biochemical abnormalities in the ileorectal group suggests continued disease activity in the distal ileum or rectum despite apparent good health. After panproctocolectomy for Crohn's disease, a high incidence of delayed peritoneal healing and occasional dyspareunia, due to scarring in the perineum, favor ileorectal anastomosis. In addition, sexual problems on the order of 5-10% may arise in men after proctectomy. It is concluded that ileorectal anastomosis is useful for the treatment of diffuse colonic disease, particularly if the ileum is uninvolved.

9175 RESULTS OF TREATMENT OF CROHN'S DISEASE WITH BCG. (Fre.) Dupuy, R.; Bernades, P.; Vallin, J.; Desouches, G.; Boulard, Ch. (Hopital Beaujon, 100, bd General Leclerc, 92110 Clichy, France). *Sem. Hop. (Paris)* 50(52/53):3147-3155; 1974.

The *Bacillus Calmette-Guerin* treatment of Crohn's disease in eight patients is reported. The attenuated BCG had been exposed to heat for 1 hr at 90 C. A 30-yr-old man with progressive disease since age 12, which was refractory to corticotherapy, showed a regression of pain and diarrhea and radiological improvement within 1 yr after BCG administration. A 21-yr-old woman received BCG in weekly doses for 6 months, followed by bimonthly doses for another 6 months. There was a rapid disappearance of the clinical signs, but a radiological cure was delayed for 2 yr. Several months of BCG therapy in a 35-yr-old man with a 10-yr history of occlusive disease had no effect. BCG treatment for 1 yr in a 30-yr-old man with relatively recent ileocecal progressi
led to a rapid clinical and radiological remission
the patient refused subsequent therapy after a
sudden symptomatic renewal. A clinical and radiological cure was achieved in a 55-yr-old woman aft
7 months of treatment. A 53-yr-old woman with a
progressive history of malabsorption, anemia, electrolytic disorder, and intestinal bleeding receive
BCG for 1 yr, with clinical and radiological impro
ment for 5 months. She succumbed to a fatal septi-
cemia after 5 months. BCG administration in a 29-yr-old man, in whom an ileotransversostomy and
prednisolone had elicited only transient relief, l
to satisfactory clinical amelioration after 10 mon
of therapy without radiological improvement. BCG
management for nearly 1 yr in a 43-yr-old man with
a history of jejunal resection was associated with
the onset of signs of acute appendicitis. BCG
appears to be ineffective in frank occlusive disea
and it may lead to intestinal obstruction, which
may require surgery.

9176 CROHN'S DISEASE IN CHILDREN. REPORT OF 11 CASES. (Fre.) Paris, J.; Blanckaert
D.; Paris, J.-C.; Morel, P.; Delattre, P.; Farriau
J.-P.; Fontaine, G. (Clinique pediatrique, Cite
Hospitaliere, 59000 Lille, France). *Ann. Pediatr.*
(Paris) 23(4):309-323; 1976.

The case histories of 11 children (7 boys and 4
girls) with Crohn's disease are summarized. Among
the prodromal signs or symptoms, weight loss and
diarrhea were most frequent, followed by hyperther
mia, diagnosis after appendectomy, abdominal pain,
hypochromic anemia, and anal lesions. Delayed
puberty, menstrual irregularity, erythema, and hyp
plastic tooth enamel were contingent signs. Infla
matory syndromes were marked by an accelerated
sedimentation rate, increased α-2- and γ-globulin,
elevated fibrinemia, positive C-reactive protein,
and leukocytosis. Radiological localization included the ileum and right colon (3 cases), the
ileum and Bauhin valve (2), the terminal ileum onl
(3), and the entire colon (3). Radiological signs
were hypertrophied Peyer's patches (follicular jej
itis), the string sign, stenosis and dilation
(ileal stasis), and the classical modifications of
distal, intermediate, and proximal segments on the
same loop. Fistulization was frequent, including
intramural fistulas. Colon involvement occurred i
8 of 11 patients, preferentially on the right (6 o
11). Favorable prognoses were established in 6 of
11 patients after the following treatment modaliti
right hemicolectomy and ileal resection, right hem
colectomy extended to the transverse colon, cortic
and immunosuppressant therapy, corticoids and anti
bacterial agents followed by total colectomy, and
antibacterial agents plus secondary colectomy. Th
results of *Bacillus Calmette-Guerin* therapy remain
equivocal. Intestinal resection is still the meth
of choice.

7 REGIONAL ENTERITIS (CROHN'S DISEASE) IN
CHILDREN AND YOUNG ADULTS. (Ger.) Brun-
, H.; Dill, J.; Hauke, H. (Olgahospital, Bis-
kstr. 8, D-7000 Stuttgart 1, W. Germany).
tsschr. Kinderheilkd. 124(5):377-379; 1976.

nostic and therapeutic experiences with pediat-
regional enteritis (Crohn's disease, CD) are re-
ed. The clinical sample included nine boys and
girls, 6 weeks-15 yr of age. Two patients
ented with acute benign ileitis, and 12 with
Clinical and radiological confirmation of CD
established in one case, but the histology
clearly ulcerative colitis; a subtotal ileo-
ctomy was required. In all cases, the extra-
stinal symptoms included fever, weight loss,
growth arrest, while the intestinal symptoms
predominantly anorexia, abdominal pain, diar-
, nausea, and vomiting. Radiologically, the
inal ileum was involved in six cases, the colon
ne, the jejunum and terminal ileum in one, and
terminal ileum and colon in seven. Involvement
he rectosigmoid mucosa, including injection,
a, inflammation, and ulceration, occurred in
cases. All patients had elevated sedimenta-
rates and left shift. Most were anemic, and
t had a leukocytosis. Salicylazosulfapyridine
g/day) was administered to all patients.
lemental prednisone (2 mg/kg/day) and azathio-
e (4-5 mg/kg/day) were given to seven and two
ents, resp. Clinical healing was obtained
our and radiological cure in three cases; the
inder showed mixed improvement and exacerbation.
e patients were radiologically and clinically
d; two of them had acute ileitis, and only one
authentic CD.

ULCERATIVE COLITIS AND CROHN'S DISEASE OF
THE COLON—A COMPARISON OF THE LONG TERM
OPERATIVE COURSES. (Eng.) Fawaz, K. A.; Glotzer,
.; Goldman, H.; Dickersin, G. R.; Gross, W.;
erson, J. F. (Beth Israel Hosp., Boston, MA).
roenterology 71(3):372-378; 1976.

hundred seventy-six patients with colitis and
colitis of unknown etiology from two previously
rted series were combined, and the follow-up
ies were extended to compare the long term post-
ative courses of ulcerative colitis (UC) and
n's disease of the colon (CDC). The combined
es provided a mean postoperative follow-up period
UC of 14 yr (5-31) and for CDC of 13.1 yr (5-36).
e were highly significant associations between
rally accepted clinical and distributional fea-
s of UC and CDC and microscopic findings general-
egarded as reliable for each. However, because
ectrum of features was found in each entity,
her clinical and distributional nor microscopic
ures alone are sufficient for diagnosis in every
. There were no differences in gross or disease-
ted mortality in UC and CDC whatever the method
iagnosis. After anastomotic procedures in CDC,
currence rate of 73% was found. After proctoco-
omy, the ileostomy revision rate (considering
types or those which required further excision
leum) was higher in CDC than UC, whether the
diagnoses were based on microscopic, clinical, or combined criteria, but the differences reached statistical significance only in the comparison of clinical UC (revision rate, 21%) with clinical CDC (revision rate, 40%). Moreover, after the first two postoperative years, the risk of having an ileostomy revision in UC and CDC (combined criteria) per patient year follow-up was identical, and there were no cases of short bowel syndrome. Differences in the clinical courses of UC and CDC after colectomy and ileostomy are of degree and do not reflect the ultimate course or potential for rehabilitation. Decisions regarding surgical therapy should be made independent of the diagnosis of UC or CDC.

9179 IN VITRO STUDIES OF INFLAMMATORY BOWEL DISEASE: SURFACE RECEPTORS OF THE MONONUCLEAR CELL REQUIRED TO LYSE ALLOGENEIC COLONIC EPITHELIAL CELLS. (Eng.) Stobo, J. D.; Tomasi, T. B.; Huizenga, K. A.; Spencer, R. J.; Shorter, R. G. (Mayo Medical Sch. and Foundation, Rochester, MN). *Gastroenterology* 70(2):171-176; 1976.

The ability of peripheral blood mononuclear cells from patients with either Crohn's disease or ulcerative colitis to lyse isologous or allogeneic colonic epithelial cells was studied. Using the ability of thymus-derived (T) lymphocytes to bind sheep RBC to their surface and the property of bone marrow-derived (B) lymphocytes to display easily detectable surface immunoglobulin determinants, the cytotoxicity of these lymphocyte subpopulations was tested. Rosette-forming cells were separated from nonrosette-forming cells by sedimentation over ficoll-hypaque. Cell fractions at the top (interface) and bottom (pellet) of the ficoll-hypaque, as well as control cells that were separated and recombined, were treated with Tris-buffered NH_4Cl to lyse the sheep RBC. Mononuclear cells at the bottom of the gradient, although enriched in the relative frequency of T cells, were able to lyse only 1% of the colonic epithelial cells. Cells at the top of the gradient demonstrated a fivefold decrease in the relative frequency of cells capable of forming rosettes with sheep RBC and a twofold increase in the ability of these cells to lyse the target epithelial cells. Lysis of the sheep RBC in each fraction did not affect the subsequent ability of cells to either reform sheep RBC rosettes or to bind Fl-anti-human immunoglobulin G to their surface. Thus, the relative frequency of T and B cells in the control population was similar to that noted for lymphocytes not treated with Tris-Buffered NH_4Cl (T=71%, B=20%). Inhibitory influences for cytotoxicity existing within the T-enriched populations were not demonstrated. It thus appears that the cytotoxic mononuclear cells from the patients with inflammatory bowel disease is not contained within the majority of T cells. Cell fractions demonstrating a threefold increase in their relative frequency of immunoglobulin-bearing B cells had a low cytotoxicity (9%) in comparison with cell fractions low in B cells (31.6% cytotoxicity) and with control cells (23.3%). Cytotoxicity was enriched among cell populations adhering to plastic petri dishes coated with aggregated immunoglobulin G, but not to dishes coated with immunoglobulin lacking the

Fc piece. This implies that the effector cell bears a surface Fc receptor. Therefore, as regards surface receptors present on the effector cell, the *in vitro* lysis of colonic epithelial cells appears to resemble most closely antibody-dependent, cell-mediated cytotoxicity.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $35.35 (this includes index issue); foreign, $8.85 additional. Single copies are $2.55, and the index issue is $4.75. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.
